The Skene Monument.—The monument of the late Dr. Alexander J. C. Skene, which is now being erected at the western end of the Prospect Park Plaza, will be completed within six weeks. The monument will consist of a bust on a twelve-foot marble shaft, raised against a marble background, which is to bear an inscription telling of Dr. Skene's achievements. The cost of the work is to be \$5,000. This memorial will stand in the most conspicuous position that could have been assigned it in the neighborhood of the park.

Society of Sanitary and Moral Prophylaxis.—At a meeting of this society held at the Academy of Medicine, February 8, the question whether instruction in the nature and dangers of venereal diseases should be given to the men of the Army and Navy service was discussed by Col. Valery Havard, United States Army, and Medical Director George E. H. Harmon of the United States Navy. The question whether the co-operation of the national government should be enlisted on this work was discussed by Dr. Louis L. Seaman.

PENNSYLVANIA.

Personal.—Dr. Thomas Redding, Hathor, was severely injured by being thrown from his carriage when it was struck by a trolley car, February 3.

More Births Than Deaths.—According to the report of the secretary of the Board of Health, Jenkintown, with its 2,500 inhabitants, had only 25 deaths in the year 1905, or one in every 100 population. There were 15 marriages and 42 births.

Free Antitoxin.—In the few months that the system of free distribution of the diphtheritic antitoxin throughout the state has been in force, the state's death rate from that disease has been reduced almost 80 per cent. This remarkable reduction in the death rate means that instead of claiming 120 lives out of every 1,000 children or adults afflicted with the disease, diphtheria now gets only 88 victims out of 1,000.

Philadelphia.

Bequest.—The will of the late Adam W. Louth devises \$5,000 to St. Agnes' Hospital for the endowment of a free bed to be known as the "Mary Louth free bed."

Will Keep Cars Clean.—The co-operation of the Rapid Transit Company in the crusade for clean and wholesome cars has been promised by the officials of the company. It is stated that they will clean the cars daily and also disinfect them with carbolic acid spray or carbolic acid scrubbing each day.

Society Election.—At the general meeting of the Medical Society of the Woman's Hospital the following officers were elected to serve the current year: President, Dr. Frances C. Van Gasken; vice-president, Dr. Clara T. Dereum; treasurer, Dr. Miriam M. Butt; and secretary, Dr. Ellen C. Potter.

Dr. Marshall Resigns.—Dr. Clara Marshall, who for many years held the chair of materia medica and therapeutics in the Woman's Medical College, has tendered her resignation, to take effect at the close of the present session, June 1. She will, however, retain her connection with the college as its dean.

Voodoo Doctor to Hang.—The governor has fixed March 26 as the date for the execution of George P. Hoosey, a "voodoo" doctor from whom Mrs. Catherine Danz is alleged to have received a powder which is said to have caused the death of her husband. Mrs. Danz was convicted of murdering her husband and was sentenced to be hanged. The board of pardons, however, recommended that the sentence be commuted to life imprisonment.

Hospital Reports. During January 63 patients were under treatment in the Kensington Hospital for Women. The Germantown Hospital admitted 132 and discharged 92 patients. Seventeen hundred cases were treated in the different dispensaries. The Samaritan Hospital admitted 115 patients to the wards and discharged 101. Four hundred and thirty-four new patients were admitted to the dispensaries and 2,048 total visits were made to the different dispensaries.

Personal. Dr. Roland G. Cuttin presided at the third annual banquet of the Center County Association at the Hotel Majestic, February 7. Dr. John H. Musser represented the University of Pennsylvania at the annual reunion of the New England Society of the alumni of the university, held in Boston, February 6. Dr. William H. Teller will entertain the Association of ex-Residents and Resident Physicians of the Jewish Hospital at his home on February 29.

Health Report.—The total number of deaths reported for the week numbered 584. This is an increase of 13 over those reported last week and a decrease of 28 from the number reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 29; measles, 20; scarlet fever, 4; whooping cough, 8; diphtheria, 11; meningitis, 3; consumption, 52; cancer, 27; apoplexy, 23; Bright's disease, 33; suicide, 4; accidents, 19; heart disease, 49; acute respiratory disease, 120; enteritis, 29; and marasmus, 2. There were 530 cases of contagious disease reported, with 44 deaths, as compared with 507 cases and 34 deaths in the preceding week. There were 361 cases of typhoid fever, with 29 deaths, or 14 more cases and 8 more deaths than for the previous week.

VIRGINIA.

Personal.—Dr. H. Ward Randolph of Richmond has sailed from New York for Europe, where he will take postgraduate work.

Smallpox Outbreak.—Smallpox has broken out, chiefly among the negroes at Port Waltham, Chesterfield County. The public schools have been closed till all the children have been properly vaccinated. No deaths have been reported so far.

Physician's Tax Abolished.—The city license tax on physicians has been abolished by Richmond. The tax was an arbitrary measure varying from \$10 to \$100 per year, based on the supposed prosperity of the physician. The yearly income to the city was about \$4,300.

Physician Assaulted.—Dr. J. L. White, one of the leading physicians of Farmville, was murderously assaulted on the night of February 5 when returning from a call. His skull was fractured and his condition is very serious. His assailant has not yet been captured.

GENERAL.

Vaccination for the Filipinos.—The Philippine Commission has appropriated \$100,000 for the purpose of conducting vaccinations throughout the islands.

Cholera in the Philippines.—Dr. Heiser, chief quarantine officer for Manila, reports that cholera is now gradually disappearing from the province of Cavite, and apparently is establishing itself in the province of Bulacan. The bureau of health is following the disease from center to center and promptly stamping it out wherever it makes its appearance. These efforts so far have been successful, in that the disease has practically remained stationary.

Annual Report of Queen's Hospital, Honolulu.—The annual report of J. F. Eckardt, superintendent of the Queen's Hospital, contains the following: The number of patients in the hospital January 1 was 47; admitted during the year, 606; total number of patients treated, 653, as against 654 in 1904, 783 in 1903, 752 in 1902 and 817 in 1900. The number of deaths, 42 in a total of 653 patients, gives a percentage of 6.41 per cent., as against 7.8 per cent. in 1904, 6.14 per cent. in 1903, 6.12 per cent. in 1902 and 8.44 per cent. in 1901. Of the patients, 171 were natives of Hawaii; 146 of the United States; Porto Rico, 60; Germany, 43; Portugal, 40; Japan, 24; China, 22; Korea, 21; Norway, 18; England, 16; Sweden, 12; Ireland, 8; Scotland, 7; France, 7; Australia, 5; Russia, 5; Argentina, 4; Belgium, 4; Denmark, 4; Italy, 4; Spain, 4; West India, 4; Austria, 2; Canada, 2; Holland, 2; Philippine Islands, 2; India, Guam, Peru, Panama, British Guiana, Martinique, St. Helena and Nova Scotia, each 1. Sixty-two patients were refused admission. Of these 24 were suffering from pulmonary tuberculosis and 9 from other incurable diseases; while 29 were not proper hospital cases; 52 patients, after receiving treatment, left the hospital, and 10 refused to remain, although urged to do so; in 3 emergency cases the patients were found to be dead on arrival; 8 patients were sent to the Home for Incurables, and 1 was sent to the insane asylum. Of the 653 patients treated, 320 were pay patients. The number of patients in the hospital on Dec. 31, 1905, was 56, viz.: 15 Hawaiians, 2 Chinese, 2 Japanese, 2 Porto Ricans, 3 Koreans and 22 of other nationalities.

Manila Medical Society Affairs.—According to the annual report of the secretary of the Manila Medical Society for 1905, on Jan. 1, 1905, the society had 46 active and 13 associate members. During the year 17 active members were admitted, 2 members have been separated from the society (Drs. Lyons and Miclano); there have been 5 resignations from active and 7 from associate membership, and one transfer from associate to active membership. The society consists at the present time of 56 active and 5 associate members. Since its organization there have been 74 active and 15 associate members. Of the active members 12 have resigned, 4 have been separated

and 2 have died. Of the associate 9 have resigned and one has become an active member. The card index of the physicians of Manila has been kept up to date and corresponds with the list kept by the bureau of health. It shows that there are in Manila 230 licensed physicians, and that there are but 153 licensed practitioners of medicine outside the city of Manila. Of the practicing physicians in Manila about one-fourth are Americans. In the city of Manila there is one physician to about 1,000 people. The report expresses satisfaction at the increased number of Filipino physicians who have applied for membership in the society, which has on its roll Filipino, German, English, Japanese, Chinese and American representatives. Undoubtedly much interest in the society was aroused by the last annual meeting of the association, and this result is a sufficient reason for the most strenuous endeavors on the part of the members of the society to make the coming meeting and other subsequent meetings of the association increasingly interesting. There is great lack of interest, however, in the scientific work of the society. There must be some aspects of individual practice in Manila that would be interesting to the members, some points in diagnosis or treatment that could be cleared up by discussion. There is a valuable working library in the bureau of science from which much direct and collateral information could be drawn and presented to the society. There is always a chance for research work in the laboratories. The report states that there is no reason why the society should not become a great power for good in the Far East, and why it should not be a very influential factor, not only in the dissemination of the facts of medicine in general and tropical medicine in particular, but also in the institution and carrying out of such legal reforms as bear on medical work in general. With the institution of the medical school the society may have a larger sphere of influence. By the promulgation of the principles of medical ethics a great change would be wrought through the rising generation, and by taking pains to interest the students in the work of the society, a scientific and useful body of men may be trained to spread clean medical customs throughout the islands. This, after all, is the most, useful function of the society. Unscrupulous men may be turned out of the best clinics, but with the ever-present influence of a body of conscientious well-trained men, quackery may be reduced to a minimum. All this looks forward naturally to the establishment of affiliated provincial societies, in order that throughout the islands the same influences may work, and that in time better and more complete knowledge of health conditions may be accumulated. The participation of the physicians of the Army and Navy has been a continued source of pleasure and profit. The permanent resident members of the society appreciate their active assistance. The secretary states that the retrospect is comparatively bright, and the prospect brighter. The treasury is comfortable. There should be every hope for continued growth, prosperity and usefulness.

FOREIGN.

Medical College for Peking.—The Union Medical College, which was established by the five Protestant missions, was formally opened February 13.

Epidemic Cerebrospinal Meningitis in Germany.—The official bulletins state that 61 cases of epidemic cerebrospinal meningitis were reported in upper Silesia in the course of December, with 34 deaths. Several cases have also been reported from the Duisburg district.

Successor to Nothnagel at Vienna.—Nothnagel's vacant chair has been offered to Quincke of Kiel and to Strimpell, but each declined the honor. Minkowski of Greifswald and von Noorden of Frankfurt-on-the-Main were then proposed by the Vienna faculty of medicine, and late advices state that von Noorden has accepted.

Approaching International Medical Congress.—The American national committee has sent THE JOURNAL a list of the American physicians who have already signified their intention of attending the International Medical Congress which convenes at Lisbon April 19. The list is a long one and includes many prominent names. See also THE JOURNAL of Jan. 20, 1906, page 207.

International Cancer Congress.—The inauguration of the new Cancer Institute at Heidelberg next September is to be accompanied by an international "congress of cancerology." The local authorities have pledged themselves to support the cancer institute for fifty years. It was erected by popular subscriptions, Czerny heading the list with a large sum. Nearly \$200,000 has already been raised. As already mentioned, Czerny has resigned his chair of surgery and will devote his energies henceforth to the cancer institute.

Typhus in Mexico.—Dr. Hamilton of the Public Health and Marine-Hospital Service reports from Laredo that a sanitary campaign is to be inaugurated to prevent the spread of typhus fever in the City of Mexico, where it is assuming a grave character. The disease is practically confined to persons who are unable to travel, and, therefore, is not a serious menace to the United States at present.

A Layman at the Head of the Austrian Public Health Service.—The public health and sanitary service of Austria, since the death of Dr. von Kussy, has been placed in the hands of Baron Hein, a lawyer by profession. The Vienna Medical Chamber (Ärztelkammer) has presented a formal protest to the government against this appointment of a layman to a position which above all others requires medical knowledge.

German Congress of Surgery.—The thirty-fifth congress of the German Surgical Association will be held at Berlin, April 4 to 7, the date having been advanced a few days so as not to conflict with the International Medical Congress at Lisbon, April 19. The subjects appointed for discussion are: "Military Surgery in the Russo-Japanese War," with addresses by participants; "Surgical Treatment of Gastric Ulcer"; "Of High Rectal Cancer," and a general discussion of Bier's congestive hyperemia in the treatment of acute inflammations.

Cancer Research in Natal.—A local committee has been formed in Natal to co-operate with the Imperial Cancer Research Fund. The occurrence of malignant disease among such colored races as inhabit the colony and among birds, reptiles, fish and the lower animals, is being investigated. All physicians and veterinarians will be asked to give their assistance in the work, and an endeavor will also be made to enlist the sympathies of naturalists and sportsmen. The *British Medical Journal* states that all specimens suspected of cancerous disease are examined, free of charge, at the government laboratories at Pietermaritzburg.

Schaudinn Summoned to Hamburg.—F. Schaudinn of Berlin has been working lately in the Hamburg Institute for Tropical and Ship Diseases, under commission from the Imperial Council of Health. The Hamburg authorities have now decided to invite him to become permanently connected with the institution, the official title of which is the "Institut für Schiffs- und Tropenkrankheiten." He is to be assistant in zoology with a salary of 9,000 marks (about \$2,250), and a pension later. The sum of \$14,250 has been appropriated to enlarge the institute. Schaudinn's fame as an authority on protozoa was so well established that when he announced the discovery of the *Spirochæta pallida* the world stopped at once to listen, while the words of a lesser authority might not have attracted attention for some time.

Reservoir Leakages and Fever in Bombay City.—The Malabar Hill and Bhandarwada reservoirs in the city of Bombay have leaked for some time and the surrounding areas of ground have been soddens and swamped. The Indian correspondent of the *Lancet* states that associated with this condition these surrounding areas have been fever-stricken and the corporation has now called for a report. Since 1901 the health department has kept the tanks themselves free from mosquitoes, but the danger covers a much wider area. All the pools, surface collections of water as well as the wells and drains must be treated by an active antimosquito campaign pending the repair of the huge reservoirs. The anopheles mosquitoes have been found in nearly all parts of the city, but the pools and swampy places occasioned by these leakages have been their chief breeding grounds.

Von Bergmann Made Senator for Life.—Kaiser Wilhelm has recently appointed von Bergmann member of the upper house of parliament (Herrenhaus) for life. This is the first time that such an honor has been conferred on a member of the medical profession. Küster of Marburg and Förster of Breslau are members of the house, but were elected as representatives of their university towns. Ernst von Bergmann was born in Russia in 1836, and was professor at Dorpat until invited to the chair of surgery at Würzburg in 1878. He served through the Franco-Prussian war and also through the Russo-Turkish campaign in 1877. In 1882 he was called to Berlin to Langenbeck's vacant chair, where he has since been. He is one of the publishers of the *Archiv. f. Klin. Chirurgie*, as also of the *Centralblatt* and of the *Sammlung f. Klin. Vorträge*, and has long ranked as one of the leading surgeons in the world, and as an able writer on surgical topics.

Plague in Japan.—Passed Assistant Surgeon Moore reports from Yokohama that plague continues to prevail in Osaka and Kobe. No new cases of this disease are reported from Shimomoseki, but a doubtful case is said to have occurred in Nara. The authorities are conducting an active antiplague campaign,

involving considerable expenditure. In Yokohama conspicuous posters are displayed announcing an increase in the number of prizes in the lotteries held for the benefit of captors of rats. Professor Kitasato recently delivered a lecture in Yokohama on plague prophylaxis, advising the dispatch of Japanese officials to India for duty in the consulates there, for the purpose of strictly examining into the sanitary condition of freight shipped from that country to Japan. In support of his position, Professor Kitasato cited the fact that the United States, with a view to keeping out sufferers from eye disease, requires the medical officer stationed in Yokohama to examine the eyes of passengers before embarkation.

Barbieri Endowment at Vienna.—Dr. D. Barbieri, who died recently at Vienna, bequeathed 300,000 kronen (about \$75,000), to the university to endow stipends for needy medical students at the first and second surgical clinics. Each beneficiary is to receive \$500 a year for three years; the endowment will thus provide for six of these stipends. He qualified his bequest with the condition that it is to be called the "Billroth Endowment," in memory of his beloved chief, Billroth. An obituary notice in the *Wien, klin. Wochtsch.* states that he was known as Billroth's "faithful Domenico," and always accompanied him when Billroth was summoned away from home for important operations. He was his assistant at the famous first resection of the stomach, and was also the first to introduce massage into Austria from Amsterdam, where Metzger had revived the ancient art of kneading the tissues. Barbieri was also renowned as an anesthetist, scrupulous of his fame that he had never lost a patient from this cause. He was further distinguished by the fact that he never wrote a line for publication and never occupied an official position, although one of the most popular physicians of Vienna. He was especially skilled in the art of keeping hope alive in the hearts of incurable patients.

Endowment of Medical Institutions to Commemorate the Silver Wedding of the Emperor and Empress of Germany.—Our German exchanges report a number of new medical institutions planned to commemorate the silver wedding anniversary of the royal pair. Berlin has appropriated \$25,000 for a tuberculosis sanatorium, and Mülheim and Schöneberg and Solingen have made similar appropriations. Magdeburg has appropriated \$25,000 for a children's hospital, and Berlin has made arrangements for a model institution for the scientific study of means to reduce infant mortality. The suburb of Charlottenburg has donated a spacious tract of land for the new institution. It is planned for fifty or sixty beds, and will be divided into a number of departments. Women will be received during the last three months of pregnancy. They then enter the maternity, and in two weeks pass to the mothers' department, where they remain three months. Infants which have to be artificially fed are received into another department to which children from outside are also admitted. A ward for sick children will also be provided, and after the mothers leave the institution they can return for consultation at stated periods. In this latter department, similar to the "infant consultations" of France and the one now in operation in Philadelphia, advice will be given to prospective and to nursing mothers, and prizes will be given for nursing and milk distributed. A model dairy and ample chemical and bacteriologic laboratories will complete the institution. Professor Heubner and the president of the Imperial Council of Health were mainly instrumental in the founding of this model Infants' Home. Vienna has already a similar one on a smaller scale in successful operation. It is the work of a local charitable society called "Infant Protection."

Ideals Proposed for the Organized Medical Profession in France.—Julien Nair's article on this subject is quoted in the *Presse Médicale*, No. 103, and we translate the latter part entire as his suggestions have attracted considerable attention: "If, as we hope," he says, "this movement for closer organization spreads throughout the physicians of France, the now isolated medical societies, when they become federated or united, may be able to play a most important rôle in the future. They will not restrict themselves merely to the defence of the profession and its members, they will form in the body politic a free institution which will, little by little, gradually assume all the official medical functions. A few years ago the authorities of the *Lot-et-Garonne* department placed the entire task of organizing the free medical assistance for the department. This example may be followed by others, and gradually the local authorities will give up more and more to the organized profession in the various departments the entire system of free medical aid, even including the hospitals. The French law authorizes the departmental

medical associations to give advice to the authorities on matters concerning their profession. What concerns the medical profession is a vast field, embracing all that pertains to hygiene and the care of the sick. The medical associations should be able to reply competently to questions asked them, and they should solicit such questions as occasion arises. The medical associations then will not be mere scientific nonentities whose advice is absolutely disregarded by the authorities when they think to ask for it; they will be powerfully organized bodies which will force the hand of the local authorities by the influence which each one of their members exerts on public opinion. Without dropping into commercialism, the departmental medical associations, with the resources at their disposal, might erect a number of scientific establishments which would facilitate the exercise of their profession and benefit their patients. . . . The local and state medical societies will no longer appear as merely works for timid defense, but will become universally regarded as beneficent institutions, indispensable to the welfare of the public. The physician who holds himself aloof from his confrères under the new order of things will find himself at such a woeful disadvantage to the others that he will haste to join. We recognize the fact that these ideals will not all be realized in our day and generation, but we are certainly beholding the dawn of an evolution of this kind. The premonitory symptoms are already apparent. Medical students used to live apart, meeting only at restaurants and similar public places. Care for the future was the least of their preoccupations. We have seen how in the last few years they have organized into associations for friendly intercourse, and quite recently have taken another forward step in organizing and supporting nobly a professional association, the "Corporative des Etudiants de Médecine," at Paris. The young physicians trained in this new association will bear with them into the practice of their profession a new spirit of organization. The young blood pouring into the local and state medical associations will revivify them, and what we now regard as an impossible ideal will be the practical reality of to-morrow." In France and Germany the physicians throughout the country are officially grouped in regional medical associations called syndicates or medical chambers ("syndicats" and "Ärztelkammer"). These organizations are entirely distinct from the scientific medical societies that may or may not be organized. They are solely for the regulation of matters affecting the profession materially or socially. They have been described more fully in these columns on page 1435 of volume xlii, 1904. The American Medical Association is so broad in its scope that it practically includes all that is meant by these foreign syndicates and medical chambers as well as all the local and general scientific organizations.

CANADA.

Personal.—Dr. P. H. Bryce, chief medical officer of the Department of the Interior at Ottawa, is in Vancouver, taking over the Detention Hospital in that city.—Dr. Mason W. H. Pitman, Montreal, has been appointed resident physician at the St. Lawrence State Hospital, Ogdensburg, N. Y.

Vancouver Association and Patent Medicines.—The Vancouver Medical Association is taking active steps to have legislation passed in British Columbia to regulate the traffic in patent medicines, and will have the hearty co-operation of the secretary of the Provincial Board of Health, Dr. C. J. Fagan, who has been instructed by the government of British Columbia to act in the matter.

A New Dispensary for Women.—A new dispensary for women only was opened in Montreal on February 1. It will be conducted by women physicians. Dr. Grace Ritchie England, assisted by Dr. Helen Macdonald, will hold a special clinic for diseases of women on Mondays and Thursdays. The clinic will be a free one, but a small sum will be charged for medicines and dressings.

New Medical Society Formed. The Essex County (Ont.) Medical Association was formed January 26 at Windsor, Ont. Dr. James Brien, Essex, was appointed honorary president; Dr. Hughes, Leamington, president; Dr. Samson, Windsor, vice-president, and Dr. McKenzie, Kingsville, secretary-treasurer. All the physicians in Essex County will be canvassed and an endeavor will be made to unite the entire profession in that county.

Prevalent Diseases. Typhoid fever is decreasing in Montreal, only 18 cases having been reported in the week ending January 27. There were only 96 cases of diphtheria in Toronto in January, 1906, against 187 in the same month in 1905; 25 of scarlet fever against 48, and 12 of typhoid fever against 14 in 1905. Smallpox is reported on the Indian re-

serve near Vernon, B. C., and Dr. Fagan, Victoria, has gone to investigate.—There is an epidemic of typhoid fever at Fort William, Ont., and it has been necessary to place from 20 to 30 patients in the contiguous hospital of Port Arthur.—Smallpox of a mild type is said to be present at La Riviere, Manitoba.

For a National Sanitarium.—Lord Strathcona, the Canadian high commissioner in England, has written Dr. C. J. Fagan, secretary of the Board of Health of British Columbia, expressing his willingness to contribute to a national sanitarium, where patients with tuberculosis might be gathered together at some point in Canada most suitable for the purpose. Dr. Fagan has been in communication with the different boards of health in Canada, and once the health authorities of the respective provinces and the general public evince a desire to participate in such an undertaking, the movement will be started and Lord Strathcona would then demonstrate that he takes a lively interest in the tuberculosis problem in Canada.

Hospital News.—The fund of the Toronto General Hospital now amounts to \$1,113,886, the County of York, in which Toronto is situated, having contributed \$15,000.—The total number of patients treated in the Winnipeg General Hospital during the week ending January 27 was 360; of these 224 were men, 94 women and 42 children.—Grace Hospital, Toronto, admitted 106 patients in January. There were 14 births, 11 deaths and 100 patients discharged during that month.—A new ward has recently been added to the Provincial Hospital for the Insane at New Westminster, B. C.—The Manitoba government has given a tract of land containing 1,500 acres for the purposes of a consumption sanatorium at Holland, Man.

Quarterly Meeting of the Ontario Board of Health.—The Ontario Board of Health held its regular quarterly meeting, which was also the annual meeting, in Toronto, January 31 and February 1, 2 and 3. A resolution was unanimously passed advising the government at once to proceed to the establishment of a department of public health for Ontario. At present health matters are administered under the department of the provincial secretary and the minister of agriculture, although it is hard to understand what a minister of agriculture knows about public health. Drs. Kennedy and Oldright, the two senior members of the board, were appointed to represent the board at the approaching International Medical Congress at Lisbon.

LONDON LETTER.

A New Plague Prophylactic.

A preliminary report by Dr. Klein to the local government board on a new plague prophylactic has just been issued. Dr. Klein found that in animals dead from plague when all the bacilli contained in their organs had been killed in the process of drying, emulsions made from the dried material and injected into mice and rats were capable of causing death within twenty hours, with symptoms like those of acute plague, though after death the tissues did not contain the bacillus. He also found that the injection of an amount of emulsion insufficient to cause speedy death produced an illness from which the animals usually recovered. When these animals were then injected with virulent cultures of the bacillus they proved refractory to infection. He concluded, therefore, that the dried organs of animals dead from plague contain a powerful plague toxin which, in appropriate doses, may serve as a prophylactic. Dr. Klein then injected into a series of animals the dried organs (containing organo-toxin and dead bacilli) of various rodents dead of plague with the purpose of ascertaining the protective power of these materials for similar rodents against subsequent infection. Many experiments were made in order to find the best methods of preparing and preserving prophylactic material as well as to determine what portions of the body of an animal dead of plague are the most efficacious. He found that a variety of tissues taken from guinea-pigs dead of subacute plague, finely minced aseptically, spread out in thin layers, on sterile glass dishes, and dried over sulphuric acid at from 46 to 47° C., yield a material which can be rapidly and easily prepared, is of uniform efficacy, and is superior in every way to other prophylactics. A guinea-pig yields from 5 to 7 gm. of dry powder prepared from the lungs, spleen, lungs and liver. The protective dose for a rat is from 10 to 15 mgm. Three days' drying is more than sufficient to devitalize the bacilli contained in the organs. The dry scales resulting are rubbed down to fine powder in a sterile mortar. The powder is transferred to a sterile wide-mouthed bottle plugged with sterile cotton wool, which is kept for two or three days at 37° C. to complete the process of drying. The

cotton wool is then replaced by a glass stopper and the prophylactic is ready for use. It can be preserved indefinitely in a dry state by a layer of paraffin over the stopper, and when tested by culture is found sterile. In preparing the prophylactic for use it is rubbed down in sterile warmed distilled water and the emulsion thus made is injected subcutaneously. Dr. Klein has experimented on several dozen white mice, from five to six dozen guinea-pigs and over 150 rats, and finds that the animals are protected against the most virulent bacilli. He concludes that from 5 to 7 mgm. of the dry prophylactic would be a proper dose for a man. A large guinea-pig dose of subacute plague would yield from 800 to 1,000 human doses—an amount of protective material equal to from 3 to 5 liters of Haffkine's fluid prophylactic. As the latter requires from four to six weeks for preparation while the former requires only from ten to twelve days, is produced at a much smaller cost and will keep in the dry state any length of time, the advantages of Dr. Klein's method are obvious.

Action Against a Physician for Mistaken Diagnosis.

An action for mistaken diagnosis has been taken against a physician under outrageous circumstances. A woman was taken ill and after attending her for some days the physician certified that she was suffering from typhoid fever and she was removed to a fever hospital, where the disease from which she was suffering was regarded as doubtful and the physicians thought that it would take a week or longer to say whether or not she had typhoid fever. They suspected typhoid fever and thought that from the symptoms the patient's physician was thoroughly justified in reporting the case as one of infectious disease and in having the patient removed to a hospital. Ultimately it was concluded that the patient was suffering from influenza. The judge said that the action ought never to have been brought, that the physician sent the patient to hospital for proper treatment, and that she had shown her appreciation by bringing the action against him. He gave judgment against her with costs on the highest possible scale.

Premature Burial.

The London Association for the Prevention of Premature Burial has held its ninth annual meeting. The report states that the past year was the most successful yet experienced. Not only was there a larger number of members, but the demand for the association's literature had increased. An endeavor is being made to appoint qualified medical examiners to the association in all parts of the United Kingdom. As a result of a lecture by a member of the association in Stockholm about fifty persons signified their desire to form a Swedish society. Archdeacon Colley moved a resolution that the new government be requested to amend the burial laws so as to secure complete immunity from the danger of premature burial. He said that he was himself an instance of escape from premature burial when a child. He was laid in a coffin and for two and one-half days was regarded as dead, but the nurse saw a movement of his hand, a physician was called and he was restored to consciousness. Only two years ago a grave was opened in his own parish and proof was found of the body having been buried alive. From the position of the bones it was seen that the person had wrenched up the lid of the coffin and turned over on the left side. The resolution was seconded by Dr. Hadwen and adopted. Lieut.-Gen. Phelps brought forward a suggestion for detecting cases of apparent death. He said that he once suggested to a physician that a device should be introduced into mortuaries by which any movement of an apparently dead person would ring an electric bell in the porter's lodge. The reply he received was that the porter would probably die of fright if the bell rang. He proposed that the association should try to enlist the sympathy of boards of guardians, hospitals and other authorities having mortuaries. A reward should be offered by the association for the resurrection of persons supposed to be dead.

The Instruction of Civil Practitioners in Military Work.

In any large war of the future recourse must be had to civil practitioners to supplement the army surgeons. Hence the necessity for some system of training in times of peace in military duties. A number of physicians resident in London have expressed their willingness to render assistance in time of war provided they are instructed in the work which they may be called on to perform. A request for such instruction was sent to the director general of the army medical services and he has arranged for a short course of lectures and demonstrations to be given at the West London Hospital on alternate Saturdays at 4 p. m. An attempt will be made to give a broad and practical view of the subject without going much into detail.

Lunacy Action Against Doctors for \$50,000.

An action has been brought in Scotland for \$50,000 damages by a Clyde pilot against two physicians. They signed medical certificates in September, 1903, under which he was placed in an asylum for four months. He was discharged as sufficiently recovered in January, 1904, subject to certain precautions. At the trial a large number of lay witnesses testified to the man's sanity before he was placed in the asylum. Two physicians who had not seen him also gave evidence on his behalf. Evidence for the defense was given showing that he was insane and threatened to shoot a friend whom he believed to be criminally intimate with his wife, and as to his violence to his wife and son. Not a particle of evidence was given as to any reason for his suspicions of his wife, and his conduct was proved to have been riotous, irritating and dangerous. Both physicians had taken a great deal of trouble with regard to his case. They examined him repeatedly and took every reasonable measure to avoid certifying him—by medical treatment and by sending him to the country. The medical certificates were in proper form, according to the Scottish lunacy law, and the facts indicating insanity observed by both physicians were full and sufficient. On his admission to the asylum the superintendent found him to be insane. Dr. Clouston and Dr. Joseph Bell gave expert testimony as to the sufficiency of the certificates and to the urgent necessity for asylum care in the condition shown by the man on admission both for his own treatment and for the public safety. Judgment was given for the physicians against the plaintiff. The case shows the need of reform of the Scotch law so as to prevent such vexatious actions against physicians who do only their duty. In England such proceedings can be stopped by a judge *ab initio*. The action of the two physicians who gave evidence on behalf of the plaintiff has aroused much indignation and a subscription list will probably be opened to enable the profession to give practical expression to their sympathy with the defendants in the heavy legal expenses to which they have been put through no fault of their own.

School Hygiene.

The report of Dr. Niven, health officer of Manchester, contains some important suggestions on the subject of school hygiene. He points out that the education of children must fail unless they are healthy and well nourished, and that from the ranks of the under-fed comes the most abundant supply of the vicious and criminal classes. He thinks that a magnificent opportunity is offered to educational authorities for seeing that the health of children is properly looked after, and that this duty is incumbent on them, since on its performance depends the success of the educational system. The first thing necessary is a race of young women who understand in some degree the duties of a wife and mother. A girl should be grounded in certain domestic branches of knowledge before leaving school. She should know how to cook, sew and mend. She should know how to clean a house and the dangers of filth. She should learn how to clean, manage and feed infants and young children. She should know something of infectious diseases and how to act when they occur. All boys and girls should be taught the elementary principles of personal hygiene. Teachers have so many opportunities of observing their scholars at their tasks, physical exercises and games that they ought to be able to perceive when anything is seriously amiss with their health and should call the attention of the medical officer of the school. The teachers should be instructed in these duties by the medical officers, a procedure which is carried out in Manchester. Training in the management of infants and young children might be carried out in crèches, but they are not quite suitable. What is required is a central hall for teaching purposes, with rooms leading off from it. With this school should be associated a museum of feeding appliances and a teaching kitchen. With the school might also be associated a plant for the modification and sterilization of milk. Further control of the rearing of children should be exercised by means of health visitors or lady inspectors.

An Infants' Milk Depot.

Dr. Newman, the health officer of the metropolitan borough of Finsbury, has published a highly interesting account of the first year's working of a depot formed under philanthropic auspices for the supply of sterilized and modified milk. The depot was established by the Finsbury Social Workers' Association and by funds privately subscribed. It has been conducted on four definite principles: 1. Absolute control of the milk and avoidance of the blunder of sterilizing meadow milk; 2. medical supervision of the entire management of the depot and of the children supplied from it; 3. a discriminating and careful distribution of the milk to only such infants as could

not be breast-fed, and 4. a systematic study of the effect of milk on the children. The first condition was secured by the effective co-operation of the farmer who supplied the milk. The cows, the utensils and the milkers are kept in the cleanest possible conditions. Immediately after milking the milk is removed and strained through a metal screen. It is then cooled in the open air under cover and at once taken to the laboratory, where the cream is separated and three modifications are prepared, adapted to the needs of infants at different ages. It is then poured into sterilized bottles. In winter the bottled milk is Pasteurized at a temperature from 140 to 150 F. for twenty minutes; in summer it is sterilized at 212 F. for twenty minutes; in midwinter for a period of some weeks no Pasteurization or heating of any kind is done. After Pasteurization the milk is cooled to 53 F. by admitting cold water into the sterilizer and is kept at that temperature until the time of transmission by rail. In summer it is kept on ice until it is distributed. The depot has proved of substantial service in reducing infant mortality, but the use of the milk has not afforded complete protection against autumnal diarrhea. Out of 129 infants fed on it 18 suffered from the disease and 5 succumbed. Dr. Newman concludes that the virus of the disease gained access to these infants through dried dust and dirt, particularly by the use of "comforters" or dummy teats.

Medical Reciprocity with Japan.

At the last session of the General Medical Council, the motion of Dr. Norman that the medical act of 1886 should apply to Japan was carried without discussion. This recommendation of the council was approved at a meeting of the privy council in December last. This will give to Japanese physicians the right to be registered as foreign practitioners in the medical register.

Poisoning by Oil of Eucalyptus.

A man, aged 34, died at Derby from an overdose of oil of eucalyptus, a drug which is not generally recognized as a dangerous poison. He sent to a druggist for three pennynorth and drank the whole—six drams—in an equal quantity of warm water. He became unconscious and was removed to a hospital, where he died two days later. Acute congestion of the lungs was found at the necropsy. A coroner's inquest followed and the jury expressed the opinion that eucalyptus oil should be scheduled as a poison.

Pharmacology

No Longer Members of Proprietary Association.

The Kress & Owen Company, New York City, ask us to announce that they have resigned from the Proprietary Association.

Not for Honor but for Money.

One of our southern exchanges in a recent issue devotes considerable space to defending the nostrum business, proprietors and proprietary remedies. Incidentally, it applies many disapproving adjectives to the Council on Pharmacy and Chemistry of the American Medical Association, to THE JOURNAL of the Association and to the various state journals that have dared to criticize the present intolerable condition of humbug in the business of making and selling "proprietary" remedies. In its opinion: "These manufacturers are not in business just for honor and sentiment, but for the money they expect to get out of their products, and for this very reason it is a guarantee that their products will be all that scientific knowledge can produce, for they know that their purity, efficacy and scientific adaptability to the cure of disease will be put to the test by the prescriber," etc. Exactly. "These manufacturers are not in business just for honor and sentiment, but for the money they expect to get out of their products," in some cases, by lying and swindling, by fraud and misstatement, by almost every sort of graft known to the "patent medicine" manufacturer and his able "ad-smith." They can get more money from their products if they mix acetanilid, soda, etc., and sell it at an enormous profit as a "brand new" chemical than they can if they tell the truth. To find out the truth and to tell it is, in part, the task of the Council on Pharmacy and Chemistry. No honest manu-

factor who is trying to market an honest preparation in an honorable way need have the slightest fear of injury from the council. Candidly, does it not seem true that manufacturers who conduct their business for money only, and without due regard for "honor and sentiment," should receive some little investigating? Does not the result of this investigation convince one that there is, perhaps, too much graft in the business of foisting nostrums on the medical profession? Shall we try to know the truth about these things, or shall we continue to be humbugged and swindled? Is ignorance "bliss," or is it a condition dangerous to our patients and "blissful" only so far as the interests of the manufacturer are concerned?

Reasons for the Stand Taken by Physicians and by Newspapers on the Nostrum Question.

The fight on the nostrum evil recently inaugurated by the lay press was duly seconded by the National Legislative Council in its meeting at Washington (THE JOURNAL, A. M. A., Jan. 20, 1906).

The principle of procedure embodied in the crusade now being so ably conducted by Mr. Bok, namely, that of uniform legislation in the various states, was specifically indorsed. Attention was informally called at that conference, however, to the well-known fact that the active participation of the medical profession would be misconstrued and that efforts would be made by the opponents of the reform measure to show that the physicians were actuated by sinister motives. An example was the editorial which the *Cincinnati Enquirer* recently directed against the bill introduced in the Ohio Legislature. In reply to this editorial the following letter was sent:

CINCINNATI, Feb. 1, 1906.

To the Editor of the *Enquirer*.—Your editorial this morning under the caption, "And Why Not?" in opposition to the pending bill to compel the publication of formulae of "patent" and "proprietary" medicines contains two references which call for reply, viz.:

1. You say that "if the owners of these medicines are to be required to disclose to the world the secret of their compound, why not the doctors who write prescriptions in the Latin text? . . . Obviously, to compel one class to give up the secrets of their formulae and protect another in not giving them up is not what President Roosevelt calls the 'square deal.'"

In reply it is to be remembered that the prescription of the physician is to-day, under the law, the property of the man who pays for it—in other words, the patient—who is entitled either to retain the original, to make a copy of it himself or to secure a copy from the chemist who compounds it. Prescriptions are, furthermore, kept on file by the dispensing chemist, where they are accessible to all properly interested persons. The trifling circumstance that, for the sake of accuracy and brevity, some, but by no means all, prescriptions are written in Latin does not deprive their owner of a knowledge of their ingredients, for if he can not read Latin himself he can easily find some one who can. It follows, therefore, that now under the law physicians do comply with all the essentials of publicity. In view of this fact it becomes obvious that "to compel one class to give up the secrets of their formulae and protect another in not giving them up is not what President Roosevelt calls the 'square deal.'"

2. You say, in the next place, that "it would appear as if the authors might not have the public welfare so much at heart as some sinister motive not obviously associated with the health of the people."

Your inference, not expressed, but still an inference, contained in this quotation to the effect that physicians are authors of the bill now pending at Columbus is not justified by the facts. This movement comes from the people as distinguished from the medical profession and from very reputable representatives of the lay press as distinguished from both the medical press and that portion of the lay press which sells its space for the exploitation of fraudulent drugs. As a matter of fact, the incomes of physicians are increased rather than diminished by the untrained consumption of these spurious "remedies" by the public. This circumstance was recently, on a very conspicuous occasion,

hurlled reproachfully at the medical profession from lay sources as an explanation of the aloofness of that profession from the present agitation. But to publish the alleged formulae of many of these so-called remedies would lead to the exposure of their fraudulent pretensions. This, in turn, would drive them not only from the market but particularly from the advertising columns of certain newspapers. All of which prompts the observation that in opposing the proposed legislation these same newspapers "might not have the public welfare so much at heart as some sinister motive not directly associated with the health of the people."

Trusting that you will publish this communication in the interest of "what President Roosevelt calls the 'square deal,'" I am,

Very sincerely,
CHARLES A. L. REED,
Chairman of the Legislative Committee of the American Medical Association.

Of course, this communication was not published by the *Enquirer*, notwithstanding its assumed devotion to the "square deal."

Death from Overdose of "Patent Medicine."

A correspondent in British Columbia sends us particulars of the following case:

A male infant two weeks old died after having been given three drops of a preparation containing opium. The child was apparently suffering from colic and his mother gave him "a few drops (three)" of Chamberlain's Colic, Cholera and Diarrhea Remedy. The mother said that the child had seemed to be in a stupor most of the day. At the inquest the child's father testified that the remedy was given about midnight Saturday night, or early Sunday morning. The child died at 11 p. m. Sunday. On the label of the bottle it is stated that the dose for an adult is one teaspoonful and for an infant from two to fifteen drops. Dr. Fraser, the physician in attendance, testified that fifteen drops would be absolutely fatal to an infant. The coroner, Dr. E. C. Hart, addressing the jury, said:

There can be no doubt but that death resulted from misadventure or accident. The jury must find a verdict on the evidence, but may also comment on the evidence or make any rider it thinks fit to its verdict. Of course, there is much sympathy to be felt for the parents. This medicine, like other patent nostrums, is sold in drug stores to anyone and everyone, without a prescription. The bottle produced contained eight grains of opium. Without treatment the taking of that amount would be fatal to a man under ordinary circumstances. Eight grains of opium could not be sold by a druggist; it is against the law for a druggist to do so. The patent medicine bottle, however, says nothing about what the nostrum contains. The dose for an adult is given as 1 teaspoonful, and for infants from 2 to 15 drops, which would be one-fourth grain of opium and positively fatal to an infant. Two drops might not be fatal, but all we know that this infant received was three drops. Many infants have been poisoned by so small an amount of opium as that in two drops of the medicine. It is what is known as a patent medicine, and we do not know what other things it contains. Opium varies in effect. In making opium preparations the chemist analyzes the opium, and if he has a poor specimen of the drug a larger amount is used, and vice versa.

Quick medicines are made in an uncertain and irregular style, and it is quite possible the bottle of medicine Mr. Duncan had contained more opium than ordered for. On the other hand, it may be that the medicine is also standardized so that each bottle holds the same. At any rate, as far as this case is concerned it seems to have been fatal to the child. It is an anomaly of our laws that a mixture of this kind, which is positively dangerous, may be dispensed while the law is so strict about poisons. This is stated in explanation. You are only required to bring in a verdict in accordance with the evidence submitted as to the cause of death, but you have the privilege to add any rider that you may see fit to do.

The coroner's jury brought in a verdict that the child died from the effects of opium contained in Chamberlain's Colic, Cholera and Diarrhea Remedy, given to the child without knowledge of the fact that the medicine contained opium, and that death resulted by misadventure.

A Warning from Fougere & Co.

The following letter has been received:

W. J. MORRISON, JR., COUNSELLOR AT LAW,
43 BROAD STREET, NEW YORK, JAN. 29, 1906.

George H. Simmons, M.D., Council on Chemistry and Pharmacy, American Medical Association, Chicago, Ill.

Dear Sir:—Messrs. E. Fougere & Co., of 90 Hickman street, New York City, as agents for several preparations intended solely for the use of the medical profession, and to which certain registered trademark

names have been given, inform me that in the literature relating to these preparations they have given the full qualitative formulae, and in many cases the full quantitative formulae and even the *modus operandi* of manufacture.

They have also informed me that your Association proposes to make analyses of these preparations, which, together with certain comment and criticism, are to be published by the said Association.

My clients request me to state that they do not desire the publication in the proposed pharmacopeia of "New and Non-Official Remedies" of any formulae to which are added synonymous terms, stated to be identical with the preparations sold under the trademark names of the firms they represent as agents; and as counsel for the above firm I wish to warn you against the publication by the American Medical Association or the Council on Chemistry and Pharmacy of any false or inaccurate statements relating to the articles for which Messrs. E. Fongera & Co. are the selling agents. Yours truly, W. J. MORRISON, JR.

It is a pleasure to give publicity to the above letter, that our readers may know the attitude taken by E. Fongera & Co. toward the work of the American Medical Association through its Council on Pharmacy and Chemistry. Since a number of the products for which this firm is the selling agent are already advertised directly to the laity, this action is not to be wondered at. We wish to state again that the annual to be known as "New and Non-Official Remedies" is presumed to contain, as nearly as possible, only those preparations intended solely for physicians' use. E. Fongera & Co., therefore, need have no fear regarding the listing of their preparations.

Santal Midy is one of the preparations which Fongera & Co. are advertising to the public. This advertisement is reproduced (without permission) from the *Chicago American* of Sunday, Feb. 11, 1906.

Gonorrhea cured in two days! And this is an "ethical proprietary" advertised in reputable medical journals!!!

Eade's GOUT PILLS

Instantly Relieve and rapidly Cure
GOUT, RHEUMATISM, RHEUMATIC
GOUT, SCIATICA, LUMBAGO and all
pains in the head, face and limbs.

At all Druggists or
E. FONGERA & CO., Sole Agents, N. Y.

"GOUT KILLER"

This advertisement, taken from the *Chicago Record Herald*, Feb. 11, 1906, has another one; there are others, but we have no time to pursue at this time.

The Physician and the Pharmacopeia.

NEW YORK, Feb. 11, 1906.

To the Editor:—You are certainly aware that I had something to do with the present warfare against nostrums. But wholesale indiscriminate denunciation I condemned from the very beginning, and especially have I no sympathy with those who, out of sheer ignorance, try to make a bible, a fetish, out of our Pharmacopeia and want to make it an unpardonable sin to prescribe or to use anything extrapharmacopeial. How absurd this tendency is will be seen from a little illustration in a day's practice of my own. I trust it will be admitted that I know as much about drugs as the average physician and know fairly well what is best for my patient. Well, on looking over today's work I find that I washed out a man's bladder with oxyanil of mercury; I administered two injections of salicylate of mercury; I prescribed pills of tannate of mercury; I used and prescribed injections of protargol and argyrol; I used euain as a local anesthetic, and I used several times a proprietary lubricant for the sounds. Here I have used seven different substances, not one of which is official in the Pharmacopeia. Of the seven products, the first three were non-proprietary and the other four proprietary. Would anybody have the hardihood to tell me that I should not have used those substances, or that my patients could have gotten along with other agents official in the Pharmacopeia and just as good? No. In the name of commonsense, let us not become hysterical. The Pharmacopeia is a good book, it is a book of standards, but in the very nature of things it can not be a perfect book. It is generally ten years behind the times, and when it does appear it is hedged about with so many restrictions about the admissibility of some of the most valuable of our preparations that the Pharmacopeia can only be an authority as to the preparations which are in it, but it can be no guide as to the usefulness or worthlessness of the preparations which are not found in its pages.

WILLIAM J. ROBINSON, M.D.

ANSWER.—We do not believe that any one suggests that we should be limited to Pharmacopeial preparations or that the Pharmacopeia contains all that is good. The Pharmacopeia does not include articles that are proprietary in character, consequently the patented products are not found in it, at least not until the patent has expired or is about to expire. There are excellent preparations of this class on the market that will undoubtedly appear in future issues of the Pharmacopeia. Would it not be absurd to say that these preparations must not be used until they are in the Pharmacopeia? There are also excellent non-patented pharmaceutical preparations that are a credit to American pharmacy, and yet they are proprietary in character and, therefore, not in the Pharmacopeia. We certainly see no objections to their use. If all proprietary articles are to be condemned, what is the use of the Council on Pharmacy and Chemistry? Are its functions not to examine into proprietary articles and publish a list of those which come up to the standard? Our correspondent, like too many others, has set up a straw man to knock down. We acknowledge that some are using the word "proprietary" in a loose way, but we doubt if any one would suggest debarring all proprietaries. It is the frauds and the fraudulent methods of promotion that are to be condemned.

The Physician Secures the Contempt of the Thoughtful Pharmacist.

Jacob Diner, according to the *Pharmaceutical Era*, has been carrying on a vigorous campaign in New York in favor of the preparations of the Pharmacopeia and the National Formulary, and, before the meeting of the New York County Medical Pharmaceutical League, he recently made some very strong statements concerning the evils that are caused by physician's prescribing proprietary preparations instead of writing prescriptions to fit individual cases. He traces the history of the origin of this flood of proprietary preparations from the time when physicians prepared their own drugs down to the era of elegant pharmaceutical manufacture by well-established houses. He says further:

"But the human mind was ever so constituted that it could not view success without envy. The success gained by some of the manufacturing chemists by reason of original discoveries immediately brought on such a flood of so-called proprietary preparations that pharmacy sank from the position of hand-maiden of medicine to that of servant girl of the manufacturer. No professional pharmacist objects to dispensing preparations which are the outcome of discovery or original research. But when he is called on to dispense any of the numberless St. Louis chemicals, when a physician wants him to act as his private dividend developer by dispensing the original discoveries of concerns in which he is interested, then the professional pride of the pharmacist rises up and revolts. In the eyes of the professional pharmacist, the physician prescribing any of these preparations is either an ignoramus or a charlatan, or both, mostly both."

The above language is vigorous. It is worth while to know the frank opinion of the pharmacist; as we have said before, it will be of benefit to us. But Mr. Diner has more to say which it is well worth our while to quote in full:

"With chemicals, even of those protected by patent, which are really scientific discoveries, he can easily assume responsibility. Chemical tests are at his command. But what can he do with preparations which never had a chemical test and never could have a chemical test, because they are mechanical mixtures, and because the manufacturers can and do change their composition at will. The M.D. who prescribes these preparations is on a par with the customer who buys Lydia Pinkham's, or Father John's, with this difference, that the layman who takes the statements of the manufacturer for truth pays for it himself, while the doctor makes the patient pay for it and often gets a little rakeoff from the manufacturer in the shape of discount."

"Let us now view the effect which the prescribing of such remedies has on the three classes most affected."

"First comes the physician. After the detail man or the manufacturer's ad. has insulted the M.D.'s intelligence by telling him what to prescribe, the manufacturer proceeds to separate the doctor from his patients in a most ingenious manner. He tells the M.D. that to insure the genuineness of the preparation he must write for an original bottle. Right here he undermines his friend, the M.D., for before very long the article has been so well introduced by the aid of the guileless M.D. that the people buy it over the counter without paying the M.D. his fee for recommending it. This is the financial phase for the M.D."

"There is also another phase. When the M.D. has become accustomed to let the detail man think for him, he has given up medicine thinking altogether. His first impulse after diagnosing a case is to call for some proprietary remedy irrespective of what its actual constituents may be, without regard to idiosyncrasies in the patient and without the possibility of knowing what secondary effects that particular dope may produce. Often he is puzzled by what he supposes to be newly developed symptoms, which are nothing less than after-effects from some of the constituents of the (to him) unknown remedy. The effect on the patient is a matter not to be lightly passed over. We pharmacists often have occasion to judge it."

"I will relate an incident which happened not long ago in my store. A lady brought in a prescription asking for a proprietary tablet whose chemical test consists of the monogram on top. After receiving the medicine she opened the box, and on discovering that the tablets were old friends of hers which she had been buying in 25-cent boxes over the counter, she said some very uncomplimentary things about the M.D., and wound up by declaring that hereafter she would consult a doctor who wrote 'real medicine.' The evil of self-medication is largely due and directly attributed to the prescribing of proprietary preparations by the M.D."

"To compel the druggist to dispense preparations of this ilk is to rob him financially and to insult him professionally. He is compelled to stock up on forty to fifty acetanilid preparations, the numberless bromid mixtures, the legion of dope cure-alls, simply because the physician is too indolent or too ignorant to compose his own prescriptions."

Mr. Diner certainly makes some very pointed criticisms, but we are compelled to admit that there is a basis of truth for them.

Letters of Appreciation.

Dr. J. B. Carroll, Hathboro, Pa., writes:

"I have read with much pleasure and profit your department of Pharmacology, and especially the work done by the Council on Pharmacy and Chemistry in

exposing the untruthful methods of patent-medicine manufacturers and vendors. I earnestly hope you will keep everlastingly at it; for these gormandizers are barely satisfied with the blood of the innocent babe and helpless old age. Readers of these exposures have had their eyes opened as never before, and the work done by the lay and medical publications deserves the highest praise."

Dr. F. S. Spearman, Whiting, Iowa, writes:

"I have derived considerable benefit from the articles by the Council on Pharmacy and Chemistry. It is doing good work for the profession in showing us just what some of these proprietaries are. A case recently occurred in one of my families in which a woman manifested alarming symptoms of collapse after taking the ordinary dose of bromo-seltzer. I was enabled to show her what the cause was, and now bromo-seltzer is tabooed in that family."

Dr. Max Goldman, Kansas City, Mo., writes:

"No one can justly deny the evil consequences of the modern indiscriminate use of patent medicines. The evil exists, however, and a strong reason, in my judgment, is the fact that in the advertisement as well as in the sale of this rubbish there is an enormous profit. We have then to contend not only with the proprietors of the advertising media, but also with the manufacturers and owners of the quack medicines. The medical profession, being of no pecuniary benefit to the public press in most localities, makes its earnest protest to deaf ears when it attempts to convince the newspaper owners of the pernicious influence of such advertisements. Nevertheless, there is every reason to feel that the American people, so ready to learn if proper suggestions are offered them, have already decided against the use of patent medicines; if so, the task of wholly prohibiting their manufacture, sale and advertisement will be much more easily accomplished."

"As regards the part the American medical profession should play in this and similar crusades, it seems to me most natural that the county society should be ever ready to stand as an individual on questions of such vast proportions."

Dr. John Fassett Edwards, Manila, P. I., writes:

"Accept my sincere thanks for the arrangement of the matter, and likewise my very hearty New Year's greetings, with particular reference to your most excellent work with regard to the 'patent-medicine' evil—it's several steps in the right direction."

Dr. O. P. Voigt, Gillett, Wis., writes:

"Keep on with the good work and the medical profession will be something anyway by the time we get through."

Dr. George W. Rall, Pittsburg, Pa., writes:

"This is just a word of appreciation; first, for the numerous changes in binding (separate cover, index on and inside cover; number, date and page on edge of cover—all of which makes THE JOURNALS unbound still useful for reference); second, for the thorough, careful, persistent and well-thought-out campaign against improper proprietaries of all kinds."

Dr. H. F. Curtis, Fiskdale, Mass., writes:

"I am glad to see the good work you are doing."

Another Newspaper Speaks Out.

In announcing the defeat in the Mississippi legislature of the Luckwood bill, which provided that all proprietary medicines which contain over 5 per cent. of alcohol or a poison should so state on the label, the *Reveille* of Natchez, Miss., says:

"The death of this meritorious measure was brought about by the 'patent medicine' houses, which, in addition to their untiring efforts with the legislature, whipped the mercenary newspapers into line by threats."

The *Reveille* received a number of these letters, all of which, with the exception of one, demanded that the influence of the paper be used to defeat the bill. One telegram ordered that we telegraph the representatives from this county to use their influence to defeat the measure. This paper never expects to sink so low that, for the sake of a small money consideration, it will oppose a measure which is calculated to result in lasting good to the people of the state; and, instead of trying to prevent the passage of such a bill when it is again brought up, we mean to do all in our power to aid its passage."

Correspondence

Medical Forgeries.

KINGSTON, ONT., Feb. 10, 1906.

To the Editor:—In *THE JOURNAL*, February 3, there is an article on "Medical Forgeries," by Dr. Van Meter, in which the senate of Queen's University is criticised for not immediately cancelling the degree granted in 1904 to Hagen Burger. In this university, however, the rights of graduates are very carefully safeguarded, and so serious a procedure can not be undertaken except on evidence which will hold in any court of law.

In an earlier portion of his article Dr. Van Meter writes: "The Colorado medical statute has no provision for the revocation of a license except on the ground of the conviction of the licensee of conduct of a criminal nature." So it is evident that his own state board, as well as those of Massachusetts and Montana, do not find it so simple a matter to revoke even a license to practice.

The fact is that if the state board of Colorado had done its duty and convicted Hagen Burger of the criminal charge of offering false and forged evidence it would be possible on the presentation of the court record for the senate of Queen's University to cancel the degree. The senate has urged on the state board of Colorado the propriety of going on with the trial as the most direct way to bring the matter to a conclusion. Dr. Van Meter makes lame apologies for this not being done, but at the same time demands that the university convict Hagen Burger—or he will place certain disabilities on all our graduates who go to Colorado. We rely on the good sense of the profession in the State of Colorado to see that nothing so unjust is done. If necessary the matter will be laid before the Department of State.

It is true that the senate has the matter under consideration. Hagen Burger was summoned and appeared before the senate on December 20, 1905. After a lengthy trial the evidence was considered insufficient to convict and a postponement was advised by our solicitor to secure further information. It may take some time to secure this. Two members of the senate will be in Germany in a few months, and they have been asked to secure the evidence desired. The death of Dr. Herald, who was secretary of the faculty at the time Hagen Burger was here, has added to our difficulty.

Our graduates and friends may depend on everything being done to protect the dignity and honor of their alma mater, and they must be gratified to learn that none of the rights and privileges of any graduate can be lightly revoked.

For their information I desire only to add that Hagen Burger was introduced to the faculty by a physician known to be an honorable man. His name appeared in Polk's register as qualified in Montana and as a graduate of Kiel University. He attended lectures in the session of 1902-3 and failed to pass at the end of that session. He then went to Boston and engaged in practice and was known to be studying there. One year and five months later he returned and then passed the supplementary examinations and was granted his degree.

J. C. CONNELL,

Dean Medical Faculty, Queen's University.

Quinin in Cholera.

COLUMBUS, OHIO, Feb. 5, 1906.

To the Editor:—I see in *THE JOURNAL*, February 3, what I have looked for a generation—some acknowledgment of the truth that quinin sulphate is a specific for Asiatic cholera. In brief, Dr. Ussher, a medical missionary at Van, Asiatic Turkey, found himself, about a year since, in the midst of an outbreak of cholera, so severe that in the first week of its prevalence all that were seized with the disease died—100 per cent. mortality. On Saturday night at midnight he began to treat the disease according to my directions (10 gr. quinin every hour until discharges were controlled), with the result that the mortality fell to less than 10 per cent. Some of your readers may recall that in my article in the *New York Medical Journal*, Aug. 18, 1904, I set the necessary mortality from the disease at somewhere between 5 and 15 per cent., when the remedy is given by the mouth (the only way it

should be given), and, preferably, in acid solution or a powder stirred up in a table-spoonful of water, as I gave it during the epidemic in this city in 1873.

The scientific part of Dr. Ussher's statement is somewhat obscure. So far as I know, Professor Koch has only demonstrated that in strength of 1/5000 the growth of the spirilla was inhibited. Dr. J. C. Graham, at that time bacteriologist of Starling Medical College (now of Denver), at my request undertook further experimentation, by which he demonstrated that in strength of 1/2500 the germ was killed in cultures in a few minutes.

For thirty years I have been drilling into the largest average medical classes in Ohio (save those of one school) that Asiatic cholera is a very curable disease when this remedy in sufficient doses is given by the mouth; that the treatment has been discovered over and over again; that quinin is useless given by the hypodermic and intravenous injection methods, as it escapes by the kidneys, never gaining access to the intestinal canal in any sufficient amount. When your last issue arrived I had an article in course of preparation, but I shall probably now await the news from Turkey in Asia. I have written to Dr. Ussher for fuller particulars about the outbreak.

To avoid misunderstanding now or in the future, I wish to state that until after I had used the remedy in 1873 I had never heard of the quinin treatment.

ERSKINE B. FULLERTON, M.D.

Trip to Europe After the Boston Session.

WORTHINGTON, MINN., Feb. 8, 1906.

To the Editor:—No doubt there will be a number of the physicians attending the annual session of the American Medical Association at Boston, June 5-8, who will sail for Europe at the close of the session. A small party has already been formed to sail immediately after the session, and we would be glad to hear from others who are contemplating a trip, either for postgraduate work or for pleasure. The postgraduate courses in Berlin will be unusually good this year.

HENRY WIEDOW, M.D.

Association News

A Great Professional Federation.

Under the above caption the *Boston Transcript* has an editorial, January 31, on the American Medical Association and on the Boston session that is worth reporting in full. It follows:

The session of the American Medical Association, which will be held in Boston on the 6th, 7th and 8th of June next, is a matter of unusual interest not only to the physicians of the country, but to the whole community. It is forty-one years since the last Boston session of this famous organization, and the growth of the Association since 1865 has been notable. Probably no organization of professional men means so much to the community at large. The American Medical Association was founded in 1847, with the declared object of improving the standard of medical education, and by that means of raising the status of the profession, and benefiting the country. While this purpose has been kept constantly in mind, the Association has exerted itself in many other fields. It has effected important reforms in public hygiene; it has impressed on legislators the value of laws relating to the betterment of the condition of the laboring classes in tenements and factories; it has preached the wisdom of a proper medical supervision of immigration; it has urged the supreme importance of healthful surroundings and care for growing children; it has pointed out the dangers and the methods of combating contagious diseases, and in manifold ways it has added materially to the alleviation of sickness, the lowering of the death rate, the suppression of quackery and the prolonging of human life. The means to forward these useful purposes form an interesting chapter in themselves, which we purpose to comment on from time to time.

The actual membership in the Association at present is about 20,000, but this figure by no means represents all the physicians who are brought under the influence of the organ-

ization. The Association was reorganized on a broad basis in 1902, and the second article of its constitution states that "The object of this Association shall be to federate into one compact organization the medical profession of the United States, for the purpose of fostering the growth and diffusion of medical knowledge, of promoting friendly intercourse among American physicians, of safeguarding the material interests of the medical profession, of elevating the standard of medical education, of securing the enactment and enforcement of medical laws, of enlightening and directing public opinion in regard to the broad problems of state medicine, and of representing to the world the practical accomplishments of scientific medicine." The federating of the medical profession is in large part accomplished. This has been done by securing the active co-operation of the various state medical societies so as to form an organic whole. These state societies bear to the American Association a relation somewhat similar to that borne by the state legislatures to the United States Senate. The federated state societies send delegates, who constitute the House of Delegates of the American Association. At the same time there are many members of the state societies not members of the American Medical Association, so it is obvious that the House of Delegates represents many more persons than are members of the American Medical Association. The total number of American physicians thus actually represented by the governing body of the Association is roughly estimated at 46,000.

It is expected that the coming session of the Association will be the largest ever held. Fourteen or fifteen thousand persons will attend, and the physicians of Boston, with the co-operation of their New England brethren, are planning an elaborate entertainment suitable to the importance of the occasion, the dignity of the situation and the scientific and hospitable reputation of the city. When we look back on Boston's achievements in scientific medicine, and remember the work of New England physicians in the past—that here inoculation for smallpox was independently produced in 1721, that Boston furnished the first physician general in the Revolutionary armies, that in 1818 the office of surgeon general in the United States Army was created for a Boston surgeon, that the vaccination for smallpox for the first time in this country was undertaken here in 1801, that surgical anesthesia was discovered here in 1846; and when we regard the recent work in diphtheria, smallpox, scarlet fever, and in general and orthopedic surgery; the leading position always held by Harvard in medical education, the splendid traditions of our great hospitals, and the famous medical names among us, Boylston, Warren, Waterhouse, Jackson, Holmes, Bigelow, Bowditch, Howe, Homans and many more—when we recall these facts we are justified in a proper pride, and a confidence that the profession and the community will not be found lacking at this time. We may be sure that Boston physicians will respond in a way to produce a scientific entertainment of the highest merit, and we have no doubt that our public-spirited citizens generally, when called on, will co-operate in their usual generous fashion with social and financial aid.

Though the meeting is scheduled to last four days only, great numbers of our visitors doubtless will spend many weeks in this vicinity. The work of our great public institutions will attract hundreds of thoughtful persons from this country and from Europe, and the charms of New England as a summer resort will induce many to tarry with us beyond the allotted time. We feel confident that this meeting will add to the prestige of Boston as the great educational, philanthropic and scientific center of the country.

Senn Medal Essay Contest.

The Committee on the Senn Medal announces that a gold medal of suitable design is to be conferred on the member of the American Medical Association who shall present the best essay on some surgical subject. The award will be made under the following conditions: (a) The name of the author of each competing essay must be enclosed in a sealed envelope bearing a suitable motto or device, the essay itself bearing the same motto or device. The title of the successful essay and the motto or device is to be read at the session at which the award is made, and the name of the successful

author announced. (b) All successful essays become the property of the Association. (c) The medal shall be conferred and honorable mention made of the two other essays considered worthy of this distinction at a general meeting of the Association. (d) The competition is to be confined to those who, at the time of entering the competition, as well as at the time of conferring the medal, shall be members of the American Medical Association. (e) The competition for the medal will be closed on, and no essays received after, April 1, 1906. Communications may be addressed to any member of the committee, which consists of the following: A. F. Jonas, chairman, 18 Continental Block, Omaha; J. F. Binnie, 12th and Wyandotte Streets, Kansas City, Mo.; Harry M. Sherman, 1303 Van Ness Ave., San Francisco, until April 15, 1906.

Marriages

JAMES J. MCGUINN, M.D., to Miss Helen Mabel Catpoll, both of Chicago, February 14.

ADOLPH F. MORGENSEN, M.D., to Miss Alma Doepke, both of Cincinnati, January 31.

J. CHRISTY CONNIT, M.D., Windsor, Cal., to Miss Bertha Alma of Mentone, Cal., January 27.

THOMAS L. WILSON, M.D., to Miss Allie M. Carroll, both of Piedmont, W. Va., January 17.

JOHN LEONARD WRIGHT, M.D., to Miss Myrtle Davidson, both of Elbridge, Tenn., February 4.

JAMES WILEET CANADY, M.D., to Miss Jeanette Bay Ferris, both of Indianapolis, January 30.

LOYD RUSSELL MACE, M.D., Philadelphia, to Miss Agnes Biller of Trenton, N. J., February 15.

HENRY W. KUEGE, M.D., St. Louis, to Miss Rose Dorothy Bohm of Watertown, Mo., February 1.

FRANK S. BENNELL, M.D., Maple Lake, Minn., to Miss Blanche Stanford of Minneapolis, Minn., February 7.

CLARENCE J. STOCUM, M.D., Pleasantville, N. Y., to Miss Elvira Gwendolyn Evans of Tottenville, L. I., January 17.

GEORGE JUSTICE EWING, M.D., Fort Washington, Pa., to Miss Mary E. Cross of Fitchburg, Mass., at Trudeau, N. Y., January 18.

Deaths

Elisha Hall Gregory, M.D., of St. Louis, president of the American Medical Association in 1886, died at Ormond, Fla., February 11, from heart disease, aged 81. Dr. Gregory was born near Russellville, Ky., Sept. 10, 1824. He received his early education in the common schools of Hopkinsville, Ky., and Booneville, Mo., then studied medicine with Dr. F. W. G. Thomas and entered the medical department of St. Louis University, from which he graduated in 1849. In 1851 he became connected with his alma mater as demonstrator of anatomy. In 1852 he was made professor of anatomy and held this position until 1867, when he was elected professor of surgery. When the Missouri Medical College and St. Louis Medical College were merged and became the medical department of Washington University, Dr. Gregory had a large share in bringing about the consolidation. Early in his practice he became connected with the Mullanphy Hospital, St. Louis, and for many years was its surgeon-in-chief. He was a member of the St. Louis Medical Society and in 1863 its president, and was also at one time president of the St. Louis Surgical Society. Three weeks

ELISHA HALL GREGORY, M.D.

before his death Dr. Gregory went to the South on account of his health, and died there after a short illness.

De Saussure Ford, M.D. Medical College of Georgia, Augusta, 1856; the nestor of the medical profession of Augusta, surgeon on the staff of General Humphrey Marshall and later in charge of the Third Georgia Hospital, Richmond, during the Civil War; professor of anatomy in his alma mater for seventeen years and then professor of surgery; three times dean of the faculty of the college and occupying that position at the time of his death; one of the founders of the Augusta City Hospital and repeatedly chairman of the governing board; president of the State Medical Association and chief surgeon of the Georgia Railroad; identified in a marked degree with many educational, charitable and municipal institutions of Augusta, died at his home in Augusta, February 5, after an illness of ten days, aged 71. At a special meeting of the faculty of the Medical College of Georgia resolutions of respect and regret were unanimously adopted.

Samuel R. Wooster, M.D. Medical Institution of Yale College, New Haven, Conn., 1837, of Grand Rapids; assistant surgeon of the Eighth Michigan Volunteer Infantry, and later surgeon of the First Michigan Volunteer Cavalry during the Civil War; county physician for Kent County from 1872 to 1889; health officer and city physician of Grand Rapids in 1880; at one time coroner of Kent County; a member of the Michigan State Medical Society, and a charter member and twice president of the Grand Rapids Academy of Medicine, died at Butterworth Hospital, Grand Rapids, February 5, after an operation for a chronic ailment, aged 75.

Adolph Gustave Brown, M.D. Jefferson Medical College, Philadelphia, 1896; a member of the American Medical Association, the Medical Society of the State of New Jersey, Monmouth County Medical Society, and Practitioners' Society of Eastern Monmouth; eye and ear surgeon of the Monmouth Memorial Hospital, Long Branch; town commissioner of Redbank, N. J., from 1903 to 1905; designer and inventor of the Redbank sewage disposal plant, died at his home in Redbank, January 21, from cerebral hemorrhage, after an illness of a year and one-half, aged 45.

Richard Albert Terhune, M.D. College of Physicians and Surgeons in the City of New York, 1850; one of the oldest physicians of Passaic, N. J.; first president of the village of Passaic and twice thereafter holding that position; first city physician of Passaic and first president of the board of health; one of the organizers of the Passaic Medical Society and an incorporator of the Passaic General Hospital Association; secretary of Passaic County Medical Society, 1852-1854, died at his home in that city, February 5, from intestinal cancer, after a long illness, aged 77.

John Winsor, M.D. Berkshire Medical College, Pittsfield, Mass., 1865; one of the oldest practitioners in the Pawtucket Valley; a member of the American Medical Association; for several years a member of the General Assembly; a surgeon during the Civil War; health officer of Coventry and medical examiner of the first district of Kent County; died at his home in Quibnick, Anthony, R. I., February 1, after an illness of nearly a year, from pulmonary tuberculosis, aged 62.

William Edward Swan, M.D. College of Physicians and Surgeons in the City of New York, 1890; a member of the American Medical Association, New York State Medical Association, Medical Society of the County of New York, Medical Association of the Greater City of New York, and fellow of the New York Academy of Medicine, died at his home in New York City, February 3, aged 39.

Robert H. Rice, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1863; a member of the American Medical Association, president of the Sandusky County Medical Society and vice-president of the Northwestern Ohio Medical Society, the pioneer practitioner of Sandusky County, died at his home in Fremont, Ohio, February 4, aged 68.

John W. Baker, M.D. Medical College of Ohio, Cincinnati, 1883; a member of the American Medical Association, Illinois State Medical Society, Clark County Medical Society, and the Esculapian Society of the Wabash Valley; died at his home in West York, Ill., January 29, from cerebral hemorrhage, after a short illness, aged 54.

Daniel W. White, M.D. Louisville Medical College, 1878; a member of the American Medical Association, Medical Society of the State of California and San Bernardino County Medical Society, died at his home in Base Line, San Bernardino, Cal., January 23, after an illness of several years, from tuberculosis, aged 51.

James Widner, M.D. Medical Department of the University of Iowa at Keokuk, 1864; a surgeon in the Federal service during the Civil War; for twelve years county clerk of Adams County, Iowa, died at his home in Corning, Iowa, January 26, from senile debility, aged 80.

George Archie Stockwell, M.D. Albany (N. Y.) Medical College, 1866; formerly editor of the *Medical Age* and the *Detroit Medical Journal*, and later editor of *Forest and Stream*, died at Houston, Texas, January 28, from cerebral hemorrhage, after a short illness, aged 59.

William M. Hand, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1888, died at his home in Woodstock, New Brunswick, February 10, from streptococcus infection contracted while operating on a patient for puerperal sepsis, aged 42.

De Haven Sharp, M.D. University of Georgetown Medical Department, Washington, D. C., 1904, a member of the medical staff of the Washington Asylum Hospital, died from septicemia at that institution, February 3, after an illness of one month, aged 27.

Lorenzo S. Bartholomew, M.D. University of Buffalo (N. Y.) Medical Department, 1884, of Reading Centre, N. Y., died at the Buffalo Hospital, January 31, from disease of the spine, for which an operation was performed a few days before, aged 49.

Isaac Warren Sawin, M.D. Cleveland University of Medicine and Surgery, 1857, assistant surgeon in the Rhode Island militia during the Civil War, died at his home in Providence, R. I., February 1, after an illness of three weeks, aged 82.

George A. Gordon, M.D. Homeopathic Hospital College, Cleveland, 1870, of Chillicothe, Mo., died at the Women's and Children's Hospital, Kansas City, Mo., January 31, a few hours after an operation for a tumor of the abdomen.

William McKinsey, M.D. Curtis Physio-Medical Institute, Marion, Ind., 1889, a veteran of the Civil War, died at his home in Marion, Ind., January 28, from cerebral hemorrhage, after an illness of two weeks, aged 63.

James B. Littlewood, M.D. University of Georgetown Medical Department, Washington, D. C., 1868, chief of the division of chemistry in the Patent Office, died at his home in Washington, February 7, from heart disease.

Howard Halsey Young, M.D. Bellevue Hospital Medical College, New York City, 1884, died at his home in Riverhead, N. Y., January 17, after an illness of about three weeks, from nervous exhaustion, aged 44.

Joseph G. Grosscup, M.D. Hahnemann Medical College, Philadelphia, 1873, of Reading, Pa., died from cerebral hemorrhage, January 31, in St. Joseph's Hospital, Reading, after an illness of eight years, aged 58.

Reuben F. Parkhill, M.D. Albany (N. Y.) Medical College, 1870, one of the coroners of Steuben County, N. Y., died at his home in Howard, N. Y., January 26, from heart disease, after a long illness, aged 73.

John H. W. Mask, M.D. Leonard Medical School, Raleigh, N. C., 1898, a highly respected colored physician of Wilmington, N. C., died at his home in that city, February 4, after a long illness, aged 32.

Francis A. Payan, M.D. Dartmouth Medical School, Hanover, N. H., 1884, died at his home in Woonsocket, Providence, R. I., January 30, from influenza, after an illness of two weeks, aged 52.

James G. Robison, M.D. Bellevue Hospital Medical College, New York City, 1884, died at his home in Rogers, Ark., from bronchial pneumonia, January 25, after an illness of three weeks, aged 46.

Edwin F. Yohn, M.D. University of Louisville Medical Department, 1895, died at his home in Valparaiso, Ind., from septicemia contracted from a patient, after an illness of three days, aged 42.

John P. Devereux, M.D. Department of Medicine of the University of Pennsylvania, 1896, of Philadelphia, died in the Polyclinic Hospital in that city from tuberculosis, February 9, aged 35.

Isaac Jackson, M.D. Jefferson Medical College, Philadelphia, 1847, for more than sixty years a practitioner of Brownsville, Pa., died at the home of his daughter in Pittsburg, February 6.

Charles H. Pierson, M.D. Pennsylvania Medical University, Philadelphia, 1876, died at his home in Avon, Ill., January 25, from pneumonia, after a short illness, aged more than 80.

Fred H. Hunter, M.D. Philadelphia College of Medicine and Surgery, 1869, died at his home in Emmetsburg, Iowa, January 24, from heart disease, after a short illness, aged 57.

Miscellany

Francis Hamilton Hill, M.D. Medical Department of Columbian University, Washington, D. C., 1849, died at his home in Washington, January 30, after an illness of three weeks, aged 80.

Joel K. Van Kirk, M.D. Jefferson Medical College, Philadelphia, 1854, of Elizabeth, Pa., formerly a school director of that place, died at his winter home in Eustis, Fla., February 3, aged 80.

George A. Tower, M.D. Boston University School of Medicine, 1877, of Watertown, Mass., died suddenly in Cambridge, Mass., from cerebral hemorrhage, February 3, aged 60.

W. H. Miller, M.D. College of Physicians and Surgeons, Chicago, 1893, died at his home in Chadwick, Ill., January 31, from pneumonia, after an illness of one week, aged 45.

Isaac S. Meeks, M.D. Medical College of Ohio, Cincinnati, 1850, one of the oldest residents of Troy, Ohio, died at his home in that city, January 31, from senile debility.

Caroline A. Risdon, M.D. Hahnemann Medical College and Hospital, Chicago, 1884, died at the home of her daughter in Oakland, Cal., February 1, from pneumonia, aged 68.

Benjamin A. Allison, M.D. Jefferson Medical College, Philadelphia, 1844, died at his home in Decatur, Ill., from paralysis, February 6, after an illness of four months, aged 89.

John H. Fulbright, M.D. Louisville (Ky.) Medical College, 1880, of Springfield, Mo., died in Los Angeles, Cal., from tuberculosis, after an illness of several months, aged 48.

Edward C. Jungbluth, M.D. Omaha (Neb.) Medical College, 1903, coroner of Colfax County, Neb., was killed in a runaway accident near Leigh, Neb., February 9, aged 27.

Harry Stites, M.D. Medical Department of the University of Pennsylvania, Philadelphia, 1876, of Harrisburg, died in Havana, Cuba, January 25, after a short illness.

Edward S. Dalrymple, M.D. New York University, New York City, 1885, died suddenly at his home in Branchville, N. J., February 3, from heart disease, aged 43.

Hiram A. Reid, M.D. Iowa Medical College, Des Moines, 1883, died at his home in Pasadena, Cal., January 28, from pneumonia, after an illness of one week, aged 71.

Elmer Fuller, M.D. Rush Medical College, Chicago, 1902, died at his home in Adrian, Mich., from influenza, January 25, after an illness of about one month, aged 43.

Walter Wells, M. D. University of Louisville Medical Department, 1905, died at his home in Willisburg, Ky., from typhoid fever, February 5, after a long illness.

Donn V. Herren, M.D. Missouri Medical College, St. Louis, 1887, of Bloekton, Iowa, died at Corning, Cal., February 1, from cerebral hemorrhage, aged 46.

E. H. Pocock, M.D. Starling Medical College, Columbus, Ohio, formerly of Marshall County, Ind., died in Oklahoma City, Okla., January 10, aged 73.

Daniel L. Robey, M.D. (Years of Practice, Illinois, 1878), died at his home in Stewardson, Shelby County, Ill., January 20, from senile debility, aged 77.

George W. T. Hannah, M.D. Vanderbilt University Medical Department, Nashville, Tenn., 1876, died suddenly at his home in Thomaston, Ga., February 1.

Robert S. Engler, M.D. Medico-Chirurgical College of Philadelphia, 1901, died at his home in Philadelphia, February 6, from typhoid fever, aged 31.

George W. Carpenter, M.D. Eclectic Medical College of the City of New York, 1887, of Minneapolis, died at St. Paul, January 28.

D. Dalton Jacobs, M.D. New York University, New York City, 1871, died at his home in Williamantie, Conn., January 31, aged 66.

Vincent Zolnowski, M.D. New York University, New York City, 1891, died at his home in New York City, January 21.

S. T. Brothers, M.D. twice a member of the Iowa legislature, died at his home in Malvern, Iowa, January 27, aged 79.

The Heart of Neurasthenia.—Dereum says that in neurasthenia the disturbances of the circulatory apparatus consist in modification of the force and rhythm of the heart's action and in the character and frequency of the pulse; more or less marked alterations of vasomotor tonus; and perhaps the most striking, if not the most common symptom of circulatory disturbances is palpitation of the heart.

A Problem in Practical Ethics.—The local profession of probably every city in the United States, says *American Medicine*, faces a problem in practical ethics, and in the larger cities this problem is multiplied a number of times. For example: Before his sins—at least before his fellow practitioners have "found him out"—a man gets into the local medical societies and establishes a fair reputation and practice. Soon are told stories, both by patients and physicians, and dark hints, or sorry evidences of trickery appear about the man. It is found that he is playing all sorts of fraudulent games with his patients to make money; he demands visits not medically required so long as the patience of the patient and his pocket-book will endure it. He smuggles in an unnecessary operation or two. If the bill is not paid there is a legal suit or a threat of it, until the poor dupe settles as best he or she may, usually paying in full to avoid trouble and to be done with the sharper. Expensive medicines of a peculiar character, or even instruments have, perhaps, also been ordered. There has been little or no cure of the disease and, when possible, there has been only an imagined, or encouraged, sometimes even a diabolically created disease present. The scamp intimidates his patients, gets new ones, heaven knows how, and while growing from bad to worse, covers up his deviltries so dextrously that legal proof of unprofessionalism can not be got. His ways become known to censors and colleagues; each shrinks from the danger and odium of exposing him, and so the infamy goes on. The local and the general professional reputation suffers, and the good name of medicine is degraded, while disgusted patients go over to quackery, saying, "These doctors must be much alike, or they'd run such fellows out of their medical societies, or 'show them up' in some way."

Postgraduate Work at Glasgow Royal Infirmary.—The provision for postgraduate clinical teaching his hitherto been very unsatisfactory in Glasgow, says the *British Medical Journal*. That there is a distinct demand for such tuition has been amply demonstrated by the success which has attended numerous courses on ophthalmology during the past few years. These courses are held during the winter months. A further attempt to organize postgraduate courses on a large scale has been decided on by the staff of the Royal Infirmary. With the approval of the managers, the following scheme has been adopted: There will be three courses of instruction in the year; one in winter during February and March; the second in spring in May, and the third in autumn during October and November. The winter course will include special instruction in the following subjects: Diseases of the ear, diseases of the nose and throat; diseases of the skin; diseases of the bladder and kidneys; diseases of women; clinical medicine; clinical surgery; surgical technique; surgical bacteriology; electrotherapeutics and bacteriology. The spring and autumn courses will be on similar lines, and from time to time such other subjects will be introduced as may be found desirable. It is intended to make the teaching as far as possible practical and clinical. There is no doubt that the Royal Infirmary will be an excellent field for postgraduate work. There will be ample clinical material at the disposal of the staff, as, in addition to a very large outdoor department, 600 resident patients are available.

Success and Failure.—Each year hundreds of young men receive their diplomas and are supposed to be ready to attend to the ailments that afflict poor suffering humanity. The *Medico-Chirurgical Journal* says that each of these young men should ask himself what he is going to do with his life. "There are many doctors, who have achieved a high reputation in their profession, who have still made a failure of their lives. Their aims have been low. They have not had a high ideal of their profession, and as a consequence they have missed the better part of life. Mere skill in diagnosis or with the knife does not mean success in the highest sense. It is in the moral sphere that the doctor, like every other man, gains his greatest success. It is the duty of every man to make the best of what is in him. Unless he works, from a sense of duty, in this direction his successes will be merely of a tem-

poral nature. He may make a discovery or two in the practice of medicine which are of use to mankind, but he will have left no lasting impression on the world. In fact, the world would have been as well off if he had never lived, for some other man would soon have made the same little technical discovery."

Chloroform Death Without Chloroform.—Professor Raymond of Paris relates in the *Progrès Médical* for January 13 that when he was a student his professor was lecturing one day on the danger of death from chloroform and how to avoid it, talking over a patient who evidently understood little of the lecture except the words danger and death. When Raymond approached to begin to administer the chloroform the patient passed into syncope before a whiff of chloroform had been given, and it was a long time before he could be resuscitated. In a recent suit for damages for a death during chloroform administration, it was proved that the patient had been much afraid of the anesthetic and had said to one of the assistants: "You will come to my funeral, won't you?" Raymond concludes that death may occur from sheer dread of the chloroform, and that the witnesses of such an accident are not responsible for the fatality.

State Boards of Registration

COMING EXAMINATIONS.

MAINE State Board of Registration of Medicine, City Building, Portland, March 13. Secretary, Wm. J. Maybury, Saco.
CONNECTICUT Medical Examining Board, City Hall, New Haven, March 13-14. Secretary, Charles A. Tuttle, New Haven.
MASSACHUSETTS Board of Registration in Medicine, State House, Boston, March 13-14. Secretary, Edwin B. Harvey, Boston.

Kansas October Report.—Dr. T. E. Raines, secretary of the Kansas State Board of Registration and Examination, reports the written examination held at Topeka, Oct. 10-12, 1905. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 28, of whom 21 passed and 7 failed. The following colleges were represented:

PASSED.	Year.	Per- Cent.
College.	Grad.	
University of Nashville	(1905)	85
Northeastern University	(1905)	84
Missouri Med. Coll.	(1890)	77
University of St. Louis	(1905)	80
University Med. Coll., Kansas City	(1905)	88
Koosuk Med. Coll.	(1905)	75, 76
Tennessee Med. Coll.	(1899)	77

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending Feb. 10, 1906:

Wilson, William H., asst.-surgeon, ordered to proceed from New York City to Schuylkill Arsenal, Pa., on official business.
 Fauntleroy, F. C., asst.-surgeon, ordered to proceed from Fort Porter, N. Y., to New York City, and report for duty as surgeon on the transport *Sumner* during its voyage to the West Indies, and on return of transport to New York City, will rejoin proper station.
 Scott, Geo. H., asst.-surgeon, leave of absence extended 20 days.
 Hoff, John Van R., asst.-surgeon general, relieved from duty in the office of the chief of staff, to take effect Feb. 15, 1906.

Morse, Arthur W., asst.-surgeon, Baker, Frank C., asst.-surgeon, Kierstead, Henry S., asst.-surgeon, advanced from the grade of first lieutenant to that of captain, to date from Feb. 4, 1906.

The following named officers of the medical department, having reported their arrival at San Francisco, Cal., in compliance with orders heretofore issued, are assigned to duty and stations as follows:

Corbuser, Wm. H., deputy surgeon-general, will proceed to Vancouver Barracks, Washington, for duty as chief surgeon, Department of the Columbia.

Tomlinberg, H. D., asst.-surgeon, will proceed to Fort Leavenworth, Kans.

Purcell, Harry S., asst.-surgeon, will proceed to Fort Mackenzie, Wyoming.

Montis, Samuel J., asst.-surgeon, will proceed to Fort Schuyler, New York.

Le Wald, Leon T., asst.-surgeon, will proceed to Fort Slocum, New York.

Swadecy, Verge E., asst.-surgeon, will proceed to Washington Barracks, D. C., and report to the commanding officer of the General Hospital at that post, for observation and treatment.

McCaw, W. D., surgeon, left Washington, D. C., on 16 days' leave of absence.

Shaddy, Cary A., asst.-surgeon, ordered to report in person to the commanding officer, Fort Barrancas, Fla., for duty.

Smith, L. L., asst.-surgeon, assigned to duty in the Army Transport Service, and will report to the superintendent of that service at San Francisco, Cal., for duty.

Cartwright, W. H., deputy surgeon-general, granted three months' leave of absence.

Hoff, John Van R., asst.-surgeon general, granted fourteen days' leave of absence.

Reynolds, F. E., surgeon, leave of absence extended fourteen days.
 Purcell, Harry S., asst. surgeon, granted twenty-one days' leave of absence.

Hathaway, L. M., asst.-surgeon, ordered to Jeffersonville, Ind., to examine male clerks and stenographers at quartermaster's depot, to determine whether they are mentally and physically qualified for service in the Philippine Islands.

Le Wald, Leon T., asst.-surgeon, granted seven days' leave of absence.

Brechemin, Louis, deputy surgeon-general, granted leave of absence for one month, on account of sickness.

Murtagh, John A., asst.-surgeon, in addition to present duties, will take charge of the medical supply depot, San Francisco, Cal., during the absence of Lieut.-Col. Brechemin, deputy surgeon general.
 Mason, George E., dental surgeon, left Fort Montrie, S. C., and arrived at Fort Oglethorpe, Ga., for duty.

Carpenter, Alden, dental surgeon, returned to Vancouver Barracks, Washington, from leave of absence.

White, J. S., contract surgeon, left New York on transport *Kilpatrick* for Philippine service.

Carson, Samuel K., contract surgeon, left New York on transport *McClellan* for Philippine service.

Newlove, George, contract surgeon, left New York as transport surgeon on the *McClellan*, en route to Philippine service.

Long, Stephen M., contract surgeon, when relieved at Fort Duchesne, Utah, ordered to San Francisco, Cal., for Philippine service.

Leifer, John P., contract surgeon, relieved from further duty in the Philippines Division, and ordered at the expiration of his present leave of absence, to duty at Fort Duchesne, Utah.

Heredford, John R., contract surgeon, arrived at Fort Montrie, S. C., for duty.

Taney, William H., contract surgeon, left Boise Barracks, Idaho, on leave of absence for two months.

Stuckey, Harrison W., contract surgeon, arrived at Fort Assiniboine, Mont., for temporary duty.

Stevens, Robert E., contract surgeon, returned to duty at Fort Missoula, Montana, from leave of absence.

Dillon, G. Parker, contract surgeon, left Army General Hospital, Presidio of San Francisco, Cal., for treatment at Hot Springs, Ark.

Hall, Henry M., contract surgeon, arrived home, Cedar town, Ga., for two months' leave of absence.

Waddell, Ralph W., dental surgeon, left Fort Leavenworth, Kans., en route to San Francisco, Cal., for Philippine service.

Navy Changes.

Changes in the Medical Corps U. S. Navy for the week ending Feb. 10, 1906:

Bertollette, D. N., medical director, commissioned medical director, with rank of captain, from April 5, 1905.

Beyer, H. G., medical inspector, commissioned medical inspector, with rank of captain, from April 5, 1905.

Gardiner, J. E., medical inspector, commissioned medical inspector with rank of commander, from Dec. 17, 1905.

De Vallin, C. M., Thompson, J. C., and Benton, F. L., surgeons, commissioned surgeons, with rank of lieutenant-commanders, from March 2, 1905.

Carton, W. M., surgeon, commissioned surgeon, with rank of lieutenant-commander, from March 12, 1905.

McCullough, P. E., surgeon, commissioned surgeon, with rank of lieutenant commander, from June 9, 1905.

Furlong, F. M., surgeon, commissioned surgeon with rank of lieutenant commander, from June 20, 1905.

Guthrie, J. A., surgeon, commissioned surgeon, with rank of lieutenant commander, from December 15, 1904.

Orvis, B. T., surgeon, commissioned surgeon, with rank of lieutenant commander, from March 1, 1905.

Kerr, D. B., surgeon, commissioned surgeon, with rank of lieutenant commander, from April 9, 1905.

Hoyt, R. E., P. A. surgeon, commissioned P. A. surgeon, with rank of lieutenant, from May 8, 1905.

Wheeler, W. H., asst.-surgeon, detached from the Naval Station, Cavite, P. I., and ordered to the *El Cano*.

Dykes, J. R., asst.-surgeon, detached from the *Baltimore* and ordered to the *Oregon*.

McBryder, J. P., asst.-surgeon, detached from the *El Cano* and ordered to the *Oregon*.

Dean, F. W. S., asst.-surgeon, detached from the *Prole* and ordered to the *Oregon*.

Grieve, C. C., asst.-surgeon, detached from the *Oregon* and ordered to the *Prole*.

Steed, J. M., medical inspector, commissioned medical inspector, with rank of commander, from Dec. 16, 1905.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending February 7, 1906:

Kallich, P. C., surgeon, to proceed to Boston and New Bedford, Mass., on special temporary duty, on completion thereof to rejoin station at Portland, Me.

Nydegger, J. A., P. A. surgeon, granted seven days' leave of absence from February 6, under Paragraph 191 of the Regulations.

Grubbs, S. B., P. A. surgeon, bureau letter granting him twenty-one days' leave from February 2, amended to read twenty-one days from February 7.

Holt, J. M., P. A. surgeon, leave of absence granted for two months, from January 15, on account of sickness, amended so as to be effective from January 23.

Wightman, W. M., asst.-surgeon, granted seven days' leave of absence from January 26, under Paragraph 191 of the Regulations.

Monoure, J. A., acting asst.-surgeon, granted leave of absence for thirty days, from February 15.

Walkley, W. S., acting asst.-surgeon, granted twenty-five days' leave of absence from February 6.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended February 9, 1906:

SMALLPOX—UNITED STATES.

California: San Francisco, Jan. 20-27, 8 cases.
Florida: Barberville, Jan. 27-Feb. 3, 4 cases; Lakeland, 3 cases; St. Petersburg, 3 cases; Seffner, 1 case.
Georgia: Augusta, Jan. 22-23, 1 case.
Kansas: In 23 counties, Dec. 1-31, 145 cases.
Kentucky: Covington, Jan. 27-Feb. 3, 1 case.
Louisiana: New Orleans, Jan. 27-Feb. 3, 9 cases.
Michigan: Ann Arbor, Jan. 27-Feb. 3, 1 case; Detroit, 1 case.
Missouri: St. Louis, Jan. 27-Feb. 3, 1 case.
Nebraska: South Omaha, Jan. 27-Feb. 3, 1 case.
Ohio: Cincinnati, Jan. 26-Feb. 2, 5 cases.
Pennsylvania: Altoona, Jan. 27-Feb. 3, 1 case (imported); Lancaster, Dec. 30-Jan. 6, 1 case.
Utah: In 8 counties, Dec. 1-31, 111 cases.
Virginia: Norfolk, Feb. 2, 10 cases (at Crane Island Hospital, 138 cases.)
Wisconsin: Appleton, Jan. 27-Feb. 3, 7 cases.

SMALLPOX—FOREIGN.

Africa: Cape Town, Dec. 9-16, 1 case.
Argentina: Buenos Ayres, Nov. 1-30, 41 deaths.
Brazil: Pernambuco, Dec. 1-13, 42 deaths; Rio de Janeiro, Dec. 21-Jan. 7, 3 cases, 2 deaths.
Canada: New Brunswick: Kings County, Jan. 29, present; Queen's County, present; Sanbury County, present; Toronto, Jan. 13-27, 3 cases.
Chile: Antofagasta, Jan. 4, 26 cases, 12 deaths; Iquique, Dec. 24-Jan. 1, 1 case, 2 deaths.
China: Hong Kong, Dec. 16-29, 3 cases, 3 deaths; Shanghai, Dec. 27, present.
Ecuador: Guayaquil, Dec. 31-Jan. 14, 9 deaths.
Great Britain: Bristol, Jan. 15-20, 1 case, 1 death; Liverpool, 2 cases (imported).
India: Bombay, Jan. 2-9, 6 deaths; Calcutta, Dec. 16-30, 55 deaths; Madras, Dec. 16-Jan. 5, 36 deaths; Rangoon, Dec. 16-30, 17 deaths.
Italy: General, Jan. 11-18, 10 cases.
Mexico: Tuxpan, Jan. 27-30, 3 deaths (55 cases and 12 deaths in suburbs to date).
Russia: Moscow, Dec. 31-Jan. 6, 10 cases, 1 death; Odessa, Jan. 6-13, 11 cases, 4 deaths.
Spain: Barcelona, Jan. 10-26, 6 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Dec. 24-Jan. 7, 6 cases, 2 deaths.
Cuba: Habana, Feb. 2, 1 case; Matanzas Province, Feb. 5, 1 case, 1 death.
Ecuador: Guayaquil, Dec. 31-Jan. 14, 13 deaths.
Mexico: Vera Cruz, Jan. 15-20, 2 cases, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, Dec. 9-23, 3 cases, 3 deaths; Bulacan Province, Jan. 4, present.

CHOLERA—FOREIGN.

India: Calcutta, Dec. 16-30, 129 deaths; Madras, Dec. 16-Jan. 5, 13 deaths; Rangoon, Dec. 23-30, 16 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Dec. 16-23, 1 case, 1 death.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Dec. 23-Jan. 7, 18 cases, 4 deaths.
Chile: Antofagasta, Dec. 20-27, 3 cases.
China: Hong Kong, Dec. 16-23, 3 cases, 3 deaths.
India: Bombay, Jan. 2-9, 17 deaths; Calcutta, Dec. 16-30, 23 deaths; Madras, Dec. 16-Jan. 5, 6 deaths; Rangoon, Dec. 16-30, 20 deaths.
Japan: Formosa, Nov. 24-Dec. 31, 15 cases, 14 deaths.
Peru: Callao, Dec. 23-Jan. 11, 1 case, 1 death; Chiclayo, Jan. 6, present; Lima, Dec. 21-Jan. 11, 16 cases, 5 deaths; Sucre, Dec. 21-Jan. 11, 1 death; Salaverry, Jan. 6, present; San Pedro, Dec. 21-Jan. 11, 2 cases, 1 death; Trujillo, Dec. 21-Jan. 11, 17 cases, 1 death.

Medical Organization

What Can the County Society Do?

XL. MEDICAL EDUCATION.

Such a topic at first sight appears foreign to the purview of a county medical society, but such is far from being the case. It is generally admitted that there are too many medical colleges, too many medical students, and especially too many physicians whose educational attainments add no luster to the profession of medicine. In great part the remedy for these evils that are so loudly decried by the average medical man is in the hands of the organized profession. Through the Council on Medical Education the American Medical Association is endeavoring by pressure at the top to force all the medical schools to do every part of their duty at a high plane.

While this good work is progressing, the members of county societies have much they can do. In states that have high entrance requirements to medical schools the societies can see to it that they are maintained and enforced. When, as in most states, this stage in evolution has not yet been reached, the societies should work hard to have such a law enacted. After all, few men decide to study medicine who do not consult one or more physicians. In the past it has been the custom of the average doctor to feel flattered that someone else wants to be a doctor, and very often a man ill equipped for medicine has been encouraged into it, only later to fall in defeat before the hard conditions, or else to remain in the guild while lowering its average of ability. That just this phase of the subject is a proper subject for medical society discussion and action is shown by the experience of one county medical society in Ohio—Shelby. For some 25 to 30 years no young man from that county has studied medicine without his qualifications being considered by the society. The result has been few students for the schools, but those few have good educations and have given evidence of possessing some at least of the necessary qualifications. In one generation in a county with no large cities this method of supervision will work a revolution in the character and standing of the profession. As with so many other ill conditions of medical life, a powerful remedy is right within the grasp of the local organized profession—the county medical society.

Material Benefits from Work in County Society.

If the energy that is being wasted by physicians in attacking, belittling, slandering and fighting one another were devoted to work, and association in work, we should have a vastly better educated profession, and the public would receive its medical attention from gentlemen very much better qualified to give it. And they would all be better off, financially. Where one finds a small city or town in which the medical men are devoting their superfluous energies to belittling each other, there, as a rule, one finds a community with medical men below the average in ability and in financial standing; patients are being referred to some surgeon or specialist in the nearest large city, instead of being attended by some local man who is quite as good as the city specialist, or might be if he would devote his energies to his own betterment and work in harmony with his fellows.

On the other hand, where we see a similar town in which is a good, active medical society, with all the physicians in the vicinity members of it, where the men are working in harmony, where they are helping each other, where they feel that they may safely leave home from time to time and do systematic postgraduate work, there we find that patients are being referred to local physicians; that different men are taking up different lines of work and are being aided and helped by their fellow physicians. Unfortunately there are too few communi-

ties that have the benefit of a medical profession of this sort; but they do exist, and a few may be found in almost every state in the country. Why are there not more?

Association in Work.

The salutary influence of the county medical society can not be overestimated. It is here that association which is lacking in the ordinary course of the day's work may be enjoyed, and acquaintance with the other physicians of the vicinity which is so vital to an honest understanding of one another and to friendly relations may be made. The broadening influence of association, with the exchange of ideas and experiences that follows, is the most potent factor in the progress of medicine. To each we may give a little; from each we may learn something. Probably one of the truest words ever spoken was Osler's axiom, "The master word in medicine is work." Without work there is no advancement in educational equipment, in professional ability. Without work, constant, steady, never-ending work, we stagnate or drop back; and not only are we distanced in the race, but the community—or so much of it as comes under our professional care—suffers; we can not give that; ade of professional service which we should give; we become ignorant.

Just as work is essential to progress, so association is essential to work. Few men have the courage or the ability to work and study by themselves and without the stimulus of association with others similarly engaged. We do not appreciate our own limitations, our own ignorance, actual or relative, until we come into contact with others better educated or better qualified than we are. It should be considered his first and most important duty, by every physician who would deal honestly with himself and with his patients, to attend his county society and to work with his fellow-physicians for the betterment and improvement of all. The plan of making each county society a practical postgraduate medical school, as advocated by the Committee on Organization and so ably preached all over this country by Dr. McCormack, is a most valuable suggestion. It embodies the two things absolutely essential to progressive medical education and individual improvement, association and work.

Association Achievements Remarkable.

Dr. D. L. Wilkinson, Montevallo, Ala., writes: "I was a delegate at the Atlantic City session at which were passed the resolutions of reorganization. I was apprehensive. It is with extreme gratification that I now wish to say that I believe we have the best organization in the world. It has already achieved marvelous results and its possibilities are limitless. What it is accomplishing for the physician in a business way, what it is doing through its Committee on Legislation, what it is doing and has done through its Council on Pharmacy and Chemistry, what it is doing to lessen preventable diseases and to protect the public, certainly entitle it to the everlasting gratitude and the unflinching support of every regular physician throughout the length and breadth of these United States."

Society Proceedings

CHICAGO UROLOGICAL AND CHICAGO MEDICAL SOCIETIES.

Joint Meeting, held Jan. 24, 1906.

DR. WILLIAM L. BALM, President of the Chicago Urological Society, in the Chair.

Syphilis of the Male Genitourinary Tract.

DR. HENRY G. ANTHONY referred to the discovery of the *Spirillum pallidum* as the probable cause of syphilis, and said that syphilis is a great imitator of other diseases. As to chance, physicians are too prone to depend exclusively on the presence of induration in the diagnosis of chancre. They do not

consider other points sufficiently, such as outline, color, smoothness of the base, varnished appearance, etc. For years it has been recognized that it is at times impossible to differentiate between chancre and chancreoid. In Paris doubtful cases are admitted to the hospital and secretion taken from the sore is inoculated into the arm of the patient and covered with a watch crystal. If the ulcer is a chancreoid, a pustule will form in twenty-four or forty-eight hours, and microscopic examination will reveal the presence of the Durey bacillus. This, he thinks, is a dangerous method and should only be employed on patients confined in hospitals. The base of the pustule should be cauterized immediately.

The diagnosis of a chancre from epithelioma of the penis is at times difficult. Cases have been observed of patients with lesions of the penis which have been diagnosed epithelioma. The penis was amputated, and shortly afterward the secondary eruption appeared. The sudden appearance and rapid development of the lesion should protect the surgeon from this serious blunder. One of the chief difficulties of diagnosis is the fact that epithelioma of the penis is apt to develop in those who have a syphilitic history. In all cases he advises that tissue be excised and examined microscopically before the penis is amputated.

When lichen planus occurs on the integument of the genitals it is apt to assume a circinate form, when it is almost certain to be mistaken for syphilis by the general practitioner.

Syphilis of the testicle in infancy frequently terminates in atrophy. There are two forms of syphilis of the testicle in adult life—sclerosis and gumma. Sclerosis is a hyperplasia of connective tissue which may affect one or both testicles. The organs enlarge to two or three times their normal size; they are very firm and hard; they annoy the patient through their size and weight. Under treatment they subside, but frequently a recurrence takes place if the treatment is discontinued, and after several attacks the condition becomes permanent.

In gumma of the testicle, one or both organs may be affected, and there may be present a single gumma or a number. Traumatism may be the exciting cause. In one of the author's cases the patient fell downstairs and struck his testicle against the newel post. As to syphilis of the epididymis, in the early months of infection six or eight nodules may develop suddenly in the globus major of each side. Later in the disease it may assume the form of a simple inflammation with deposits of plastic material, and disappear under treatment, leaving fibrous tissue.

Cases of gumma of the cord have been reported by Campbell, Goldenberg and others. In a case observed by Verneuil, the tumor was the size of two fists and was diagnosed as carcinoma. Its specific nature was discovered on postmortem examination. Reclus reported a case in which the cord had attained the diameter of a lead pencil, and it was stiff and rigid like a glass rod. In most of the cases the lesion was an almond-sized tumor which had been mistaken for a cyst.

As to syphilis of the penis, a chancre of the meatus produces a ring of cartilaginous hardness surrounding the meatus, which, when seen before the tenth day, can only be detected by palpation. There is no change in the color of the mucous membrane; later the mucous membrane presents a whitish appearance. It is usually accompanied by a discharge from the urethra which contains the gonococcus. The author also discussed scleroderma of the meatus, papular syphilide of the meatus, gumma of the prepuce, cylindroid of the urethra (the rarest of all syphilitic lesions of the genitourinary organs), syphilis of the ureter, syphilis of the kidney, and syphilis hereditaria tarda.

Tuberculosis of the Male Genital Tract.

DR. ALEXANDER HUGH FERGUSON discussed tuberculosis of the male urethra, prostate gland, seminal vesicles, vasa deferentia, epididymes and testicles. He said that primary tubercular urethritis of penile and membranous urethra is very rare. It is almost invariably secondary, and is a part of urogenital tuberculosis, descending from the kidney, bladder, prostate, vesiculae seminales, vas deferens, epididymis and testicles; more rarely affecting the areas of physiologic dilata-

tion, e. g., the prostatic, bulbous and navicular portions of the urethra where urine stagnates. The prostatic urethra is most frequently involved, but the lesions may occur along the entire urethra. Tuberculosis here, as elsewhere, may appear in the form of a military tuberculosis, diffuse or clustered; as indolent ulcers, or cheesy infiltrations. The surface often appears diphtheritic. According to Senn primary tuberculosis of the urethra is exceedingly rare, and when it does occur it takes place in a part of the urethral mucous membrane prepared for the reception and growth of the bacillus by some antecedent injury or disease. Secondary tubercular lesions of the male urethra comprise 1 per cent. of all forms of tuberculosis and 17 per cent. of all cases of urogenital tuberculosis. Young male adults, subject to or affected with tuberculosis, are prone to tubercular urethritis. Baumgarten's experiments on rabbits are rather convincing that primary urethritis, tubercular in character, may occur by inoculation. In either primary or secondary urethritis of this nature the diagnosis is not scientifically complete without demonstrating the presence of the bacillus of tuberculosis.

In over 100 cases of prostatectomy Ferguson has observed tubercular foci in five cases where tuberculosis was not diagnosed before operation, and only suspected in the last two, owing to their clinical history. The prognosis of the prostatic cases that are obviously tubercular, whether unilateral or bilateral, acute or chronic, primary or secondary, is very grave. The course may be very slow, and it usually is, but the termination is often fatal. The treatment should be constitutional mostly. He performed a prostatectomy on three patients suffering from tuberculosis of the prostate, in what he judged to be an early stage of the disease. Two died of general tuberculosis within a year; the other lived a year and a half, then died of bilateral kidney tuberculosis. A perineal fistula persisted in one case. Ferguson stated that when an abscess forms in the prostate it should be opened in the direction it is pointing, either via the rectum or perineum.

Tuberculosis of the Male Urinary Tract.

DR. ARTHUR DEAN BEVAN said there are three common foci of so-called primary tuberculosis of the genitourinary organs. The term primary must be qualified, although the possibility of a true primary tuberculosis of these organs must be admitted in the sense that the bacilli may gain entrance into the circulation without having lodged at a point where the primary focus is developed and are carried to the kidney or to the epididymis. But such a true primary involvement is rare. In almost all cases of tuberculosis of the genitourinary organs a bronchial or tracheal gland, or some lung or bone tuberculosis is the primary focus. From this focus the tubercle bacilli enter the circulation and then lodge in the kidney, prostate, epididymis, etc. An ascending tuberculosis from the urethra is possible. Bevan thinks that the majority of writers still maintain the view that the epididymis is the common point of infection, but he thinks this view is erroneous. So far as the order of frequency is concerned, he thinks the kidney is the most common point of involvement, the epididymis second, and the prostate third.

The recent work of Semon, Kronlein, Mayo, and the speaker's own has shown that tuberculosis of the kidney, in more than 90 per cent. of the cases, is unilateral, and if the diagnosis is made early, a nephrectomy will frequently clean up the entire picture. Kidney tuberculosis is not very commonly followed by genital tuberculosis. Genital tuberculosis leads to involvement of the vas deferens, the seminal vesicles, and the prostate and bladder. Tuberculosis of the kidney very often runs a silent course, without a symptom. He has operated on a patient with a distinct, definite history of lesion of the right kidney, who before the operation believed herself to be in very good general condition. Nephrotomy of the right kidney showed a large accumulation of pus. From the time the nephrotomy was made not a drop of urine passed through the bladder. There were no symptoms referable to the opposite side at any time, but within a week the patient died. Postmortem examination showed the opposite kidney, which had never given rise to any symptoms, to be a sausage-like structure composed of a dense fibrous capsule, filled with a caseating mass, without a vestige of kidney tissue.

Such a picture of silent tuberculosis occurs not infrequently. The ordinary symptoms are very similar to those found in several other conditions—stone, malignant tumor, polycystic degeneration of the kidney, pyelitis, and nephropylitis from other germ infections. Blood is a common sign and symptom; also pus. The pain is of two kinds—colicky pain, which simulates closely that caused by kidney stone; rather chronic tenderness and uneasiness; temperature; presence of a swelling. In the advanced cases, where there is present a tubercular pyonephrosis, or perinephritic process, there is no early evidence of swelling. In the advanced cases, again, there is a general picture of tuberculosis, with temperature. The presence of tubercle bacilli is discovered in about one-third of his cases. Where the presence of bacilli is not determined the symptoms frequently can not be differentiated from those of stone in the kidney. Here Bevan employs the x-ray. If the x-ray shows stone, well and good; if it does not, he believes he has to do either with tuberculosis or hypernephroma. If there is no swelling, no enlargement, but temperature, he says, tuberculosis. If there is enlargement and no temperature, with the absence of stone, absence of tubercle bacilli, he says, probable hypernephroma, so that the diagnosis is arrived at in a number of cases by exclusion. Where one kidney is involved and the other is healthy, a nephrectomy should be done, as nephrotomies and resections are not followed by satisfactory results.

DISCUSSION.

DR. F. KREISSL expressed himself a little more optimistically than Dr. Bevan relative to the treatment of tuberculosis of the bladder. In many cases he thinks the removal of the kidney, which is the primary focus, may effect a cure of the secondary lesion in the bladder without any other interference. In secondary lesions due to a descending infection he has noticed quite often that certain topical applications to the excoriated bladder cause these ulcers to heal. He does not think that a primary lesion of the bladder, however, can be favorably influenced by the application of iodoform or bichlorid solution.

DR. GUSTAV KOLISCHER said that tuberculous cystitis may exist. Around the ureteral opening there may be a few disseminated ulcers, with undermined edges, and a few gray tuberculous nodules. In such cases favorable results are obtained if the kidney, which caused the descending tuberculosis, is removed. Rosen has recommended the injection of a 5 per cent. carbolic acid solution into such a bladder after the kidney is removed. In the case of a young girl on whom Kolischer did a nephrectomy, he found three ulcers. These healed inside of three days after the operation, but whether the healing of them was due to the injection of the carbolic acid or to the removal of the kidney, he does not know. He called attention to the fact that quite often the first symptom of kidney tuberculosis is frequency of urination. These patients, often without further examination, are treated by different methods, the urine not being examined. In young women, where the bladder is extremely tolerant, tuberculosis may exist for any length of time without causing serious symptoms.

DR. FERGUSON said that he has done nephrotomy in 12 cases, but had to remove the kidney later.

DR. BEVAN emphasized the point that tuberculosis of the kidney very frequently is primarily unilateral; and that the lesser operations of nephrotomy and resection can not be relied on; that the weight of evidence would seem to be in favor of a radical operation where an early diagnosis is made and the existence of another healthy kidney is determined.

WEST PHILADELPHIA BRANCH PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held Jan. 12, 1906.

Acute Tetanus with Recovery.

DR. GEORGE ALEXANDER KNOWLES reported the case of a boy 9 years of age, who received an incised wound of the left leg below the knee. The wound was cleansed and dressed with a bichlorid dressing and closed with four sutures. The edges did not unite and suppuration appeared. After several days the stitches were removed, the wound cleansed with bichlorid and peroxid and a 50 per cent. solution of carbolic acid in

glycerin was applied. Eight days after the accident the boy complained of painful swallowing, and the corners of his mouth became depressed. Bromid and chloral were immediately administered, but the symptoms increased, and in addition there was a slight twitching of the muscles and the jaw almost became locked. Tetanus antitoxin in doses of 30 c.c. was given hypodermatically twice daily for eleven days, in conjunction with bromids and chloral, and when the pulse was high and irregular, 5 gtt. of tincture of digitalis were given per rectum. On the thirteenth day, muscular rigidity having become constant, with convulsive seizures, opisthotonus and pleurothotonus, a lumbar puncture was made and 1 dram of antitoxin in 1 dram of normal salt solution was injected. The temperature rose to 104.3/5, but after about four days returned to normal. Food and brandy were given per rectum during the progress of the disease, and saline solution was administered in the same way in order to supply the system with water, as any attempt at giving water by the mouth produced convulsions. The pulse and respirations during the course of the disease were as high as 160 and 52 per minute respectively. On the fourteenth day the convulsions became less and finally ceased, although the muscular twitchings continued for several weeks after the patient was out of bed. They have now ceased entirely and the patient has made a good recovery.

DISCUSSION.

DR. W. S. NEWCOMET stated that at one time he felt that some of the deaths from tetanus were due to overdugging, and he decided to make sure that this should not be the case with the next patient. The patient on whom treatment was undertaken with this theory in view seemed to be progressing very nicely for several days, and one morning on going to the ward before breakfast, Dr. Newcomet learned that the patient had not had a convulsion during the night, but on returning to the ward after breakfast, he was informed that the patient had suddenly had a convulsion and died.

DR. C. B. LONGENECKER said that a man who ran a splinter of wood into his hand was first seen in the early stages of tetanus, and was immediately sent to the hospital and large doses of tetanus antitoxin were administered. At the end of ten days the spasms ceased and he was thought to be on the road to speedy recovery, when shortly afterward he relapsed into unconsciousness and died.

DR. KNOWLES stated that 720 c.c. of antitoxin were given to his patient and that the child had entirely recovered.

Modern Treatment of Wounds of the Anterior Segment of the Eye.

DR. JAMES F. PRENDERGAST stated that one of the important features was asepsis. Careful examination, with a good light, should be made and if there is redness present, the character and situation should be noted, as these are important diagnostic aids. Injuries of the lids are usually marked by free extravasation of blood, and cold compresses should be applied, if the case is seen early. If these do not accomplish the desired result, hot compresses, massage and sometimes a leech are of value. Lacerated wounds should be cleansed carefully and the edges brought together accurately to prevent deformity. Puncture wounds should be examined with great care to ascertain if there is any injury of the deeper structures, and if there is much reaction, septic washes should be applied. Burns, if external, should be treated the same as burns of any other part of the body, and if there are granulating surfaces, they should be protected with rubber or other tissue to prevent their growing together. Lacerations of the conjunctiva should be brought together with fine sutures, the edges carefully cleansed, foreign bodies picked out with sterilized instruments, and if the lacerations are painful, a drop of cocaine solution may be instilled. In burns of the conjunctiva, especially time burns, he deems thorough flushing advisable. To alleviate pain, cocaine solution and cold compresses were advised, and for the stimulation of healing hot compresses were recommended. Foreign bodies should be removed from the cornea and in many cases a drop or two of atropin is of value. Burns of the cornea should be treated by thorough cleansing of the eye and the application of cold compresses for a short time.

Syphilitic Complications of the Nose and Throat.

DR. A. B. KIRKPATRICK stated that it is very difficult to make a diagnosis of syphilis of the nose and throat in the primary and early secondary stages without inspecting other parts of the body. Suspicious cases should receive a careful examination of the tongue, hard and soft palate and throat. In the early cases there may be no history and no scars, and the vagaries of the specific infection are so irregular that even the most astute clinician may be mistaken. The secondary lesions of the throat occur most frequently in the following localities: tongue, lips, soft palate, gums and uvula. In the tertiary stage the diagnosis is more easily made, a symptom that is absolutely diagnostic being an erythematous eruption. In the treatment of syphilis he urged securing the confidence and co-operation of the patient and the necessity for continuing treatment for a sufficiently long period.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns.]

Pneumonia.

In an article in the *St. Louis Medical Review*, L. Litchfield, in speaking of the treatment of pneumonia, states that the patient should be supplied with plenty of fresh air without draughts. All unnecessary persons should be excluded from the sickroom. At the onset of the disease the digestive tract should be thoroughly cleansed by calomel or a saline purge, and water should be given freely and forced, if necessary, in the delirious patients, by high saline enemata and by hypodermoclysis. If the pain is very severe, codein or morphin combined with atropin may be used very sparingly hypodermically. If the blood pressure is high, with a hard, full, bounding pulse, bleeding may be resorted to. In other instances, aconite or veratrum viride with active catharsis and icebags to the head and chest may accomplish the same effects. When the patient is delirious, in order to guard against any possible accident he should never be left alone. As regards the diet, Litchfield recommends that the nourishment be very sparingly given during the initial stage, and states that it should be simple and easily digested, as fermentation is liable to occur in the intestine, and thus produce a very serious complication. For the reduction of temperature he recommends sponge baths or packs. The heart must be carefully examined, and with an exaggerated second pulmonic sound strychnin should be administered, and if the pulse becomes irregular or intermittent, digitalis should be used. Litchfield recommends alcohol in the form of whisky or brandy, both as a stimulant and as a food, taking the place of fats and carbohydrates. He prescribes it especially when the pulse reaches 120, and if the amount given should show its effect by being eliminated through the respiratory tract, he recommends that it be diminished. If a collapse is threatened, with accompanying cyanosis, a hot mustard bath or hot pack should be employed, with the free use of stimulants hypodermically. Hot baths and packs are used also when extreme nervousness is present. After the crisis has taken place, or in cases of delayed resolution, he increases the diet by giving eggs, chops and steaks, which may be continued steadily unless there is an evidence of the recurrence of temperature.

Mumps.

Mumps, as a rule, require but little treatment, especially in children. In grown individuals, however, considerable discomfort may arise, and occasionally the patient may suffer a great deal of pain. In some cases it is necessary to institute an active line of treatment, in order to keep down complications. The patient should be put to bed and placed on a restricted diet.

According to the *Medical Press*, an instillation of the following may be used locally for its disinfecting purposes:

- R. Menthol gr. viii 50
 Liquid petrolati ʒi 30
- M. Sig.: To be instilled into the nasal passages two or three times a day.
- As a gargle the following combination is recommended:
- R. Thymol ʒss 2
 Menthol gr. xv 1
 Alcoholis ʒiv 120
- M. Sig.: Ten to fifteen drops in half a glass of water as a mouth wash and as a gargle.
- If the fever should be of any consequence, warm baths are recommended and a preparation of quinin given internally. The following combination may be given:
- R. Quinine hydrochloratis ʒi 4
 Syrupi ideae ʒi 30
 Aquæ ʒii 60
- M. Sig.: Two teaspoonfuls three or four times a day for an adult.

Otalgia and orchitis are the two most frequent complications of epidemic parotitis, consequently when severe earache is present the tincture of opium, a few drops on a small piece of cotton-wool, and applied locally in the external ear, will usually suffice. Locally over the infected glands the following combination is recommended to relieve the pain and to cause the swelling to subside:

- R. Guaiacol ʒss 2
 Spiritus chloroformi ʒi 4
 Lanolin ʒss 15
- M. Ft. unguentum. Sig.: Apply to the parotid region, and cover with cotton and oil silk.
- If orchitis should arise poultices are recommended, which should be changed every two hours, and when the pain has sufficiently subsided an ointment similar to the following may be applied:
- R. Guaiacol ʒss 2
 Extracti belladonnæ gr. v 30
 Lanolin ʒi 30
- M. Ft. unguentum. Sig.: Apply locally.

The Bromids.

In his experiments on animals, F. Carter of Glasgow University, in an abstract in the *Critic and Guide*, states that ammonium bromid is more toxic than sodium bromid, and that with large doses the predominant action is due to the ammonia, and that with repeated non-toxic doses the effects of the bromid may be obtained. In the author's opinion, ammonium bromid is not an eligible compound, because the bromid action is only evident after prolonged administration, while the stimulating action of the ammonium is produced rapidly, but passes off within an hour. As regards the action of the potassium and sodium salts, which, according to general opinion, is about the same, with either, Bernard regards potassium as three times as toxic as sodium, and states that consequently it has a much more depressing effect on the heart. Distefano makes a statement which counteracts this general opinion, by saying that potassium salts, instead of weakening the heart, stimulate it, and according to this writer's opinion, the potassium salts are preferable to the sodium salts. The sodium salts remain in the plasma and tissue spaces, while the potassium salts penetrate into the tissue itself and into the protoplasm, and as a proof of the greater efficacy of the potassium salts, he mentions the universally admitted superiority of the iodid of potassium to that of sodium in the treatment of syphilis.

Rectal Atony.

In the treatment of defective muscular power of the rectum Bodenhamer, in the *New York Medical Journal*, states that the first consideration should be the observance of strict and regular habits regarding the daily evacuation. This may be assisted sometimes by the injection of from a half to a pint of cold water, at a regular time each day. As cold is tonic, stimulant and astringent, it acts somewhat similarly to nux vomica, by exciting the sensibility and contractility of this portion of the bowel. In more obstinate cases, however, Bodenhamer recommends nux vomica as the best remedy, given alone or combined with other preparations. Drastic purgatives should never be used, and the smallest dose of an

aperient should be given so as to arouse gently the normal peristaltic action, and this aperient should be continued only until the daily habit of evacuation is established.

With regard to the ingredients composing an astringent and tonic injection, to be used locally in the treatment of atony of the rectum, this author states that the amount should not be more than five or six ounces, and should never be administered until the rectum has been thoroughly emptied of its fecal contents by a proper enema or aperient. This astringent injection should be given once daily at least, and instructions should be given the patient to retain it for a few minutes, if possible. In obstinate cases, a half to a grain of nux vomica may be added to this injection. He recommends for injection the decoction of galls as well as a strong decoction of white oak bark and alum. The following combination is also recommended by him:

- R. Acidi tannici gr. xxx 2
 Vini rubri ʒiv 120
- M. Sig.: For one injection.
- He quotes the following combination as being recommended by Trousseau, as one which not only restores the organ to its normal action, but which will also cure anal fissure, if present:
- R. Extracti rhatany ʒii 8
 Alcoholis ʒv 20
 Aquæ dest., aa. ʒv 20
- M. Sig.: For one enema.
- In some cases the following pill or one with a similar combination is recommended, especially if the atony of the cecum exists with that of the rectum, in order to excite the peristaltic action in those parts which can not be properly reached by an enema:
- R. Ext. aloes gr. xxx 2
 Ext. nucis vomice gr. xx 130
 Ext. hyoscyami gr. xv 1
 Ferri sulphatis gr. x 65
 Olei caryophylli m. v 30
- M. Ft. pillule No. xxx. Sig.: One pill at bedtime.
- In the treatment of ordinary cases of atony of the anal sphincters, the cold water douche is recommended, applied rather forcibly for four or five minutes directly after each evacuation of the bowels. The following ointment or lotion may be used with advantage in such cases:
- R. Strychnine sulphatis gr. x 65
 Ung. aquæ rose ʒi 30
- M. Sig.: Apply a small amount locally. Or:
- R. Ext. nucis vomice gr. viii 50
 Alcoholis ʒii 60
 Aquæ ammoniæ ʒi 4
- M. Ft. lotio. Sig.: Apply locally.

Medicolegal

Court May Compel Re-exhibition of Person.

The Supreme Court of Texas has held that, where a party has not voluntarily exhibited his person to the jury, a court has no power to compel him to do so. But, in *Houston & Texas Central Railroad Co. vs. Anglin*, a personal injury case brought by the latter party, it reaffirms the rule that, where a party has once exhibited his person to the jury to show the extent of his injuries, he may be required during the course of the trial to re-exhibit them. In this case the trial judge refused to compel the plaintiff, who had given testimony in his own behalf, and during the course of his examination had voluntarily exhibited his breast to the jury, to again exhibit it to a physician who was a witness for the defendant. The physician had testified that he examined the plaintiff a short while after the accident, and that his breast was then deformed; and it was proposed to show by the witness, after examining the alleged injured part of the plaintiff, that the same condition which existed at the time of the trial existed immediately after the accident. The court holds that the ruling of the judge refusing to compel the re-exhibition constituted reversible error. It says that if the plaintiff had been compelled to exhibit again his breast in the presence of the physician, and the latter, after examining, had been enabled to say that he

saw no difference between its condition at such time and what it was at the time of the accident, the testimony would have been material.

Opinions as to Causes—Failure to Obtain Medical Aid.

The Supreme Court of Missouri, Division No. 1, says, in the personal injury case of Glasgow vs. Metropolitan Street Railway Co., that it was competent for the medical witnesses to state what cause or causes might produce such a result as that in question (apparently a displacement of the womb), and this both of them did without objection, stating that such a fall as claimed could produce it, and that there were many causes which would produce the same effect. But it was incompetent for them to say that in this case the plaintiff's condition was, in their opinion, the result of the alleged fall. It was competent for them, in giving their opinions, to speak of that which they knew from their scientific learning and experience. It was not competent for them to draw conclusions of facts from the evidence in the case. There are cases in which a physician or surgeon may give his opinion, not only as to what might produce a given result, but also as to what in fact did produce the particular result in hand. But such are cases where no other cause could reasonably have produced the effect. Instances of this kind are found in murder cases where the cause of death is the question. A dead body is found floating in the river. To the eye of the casual observer it is a case of drowning. But a man of science makes an examination and testifies that the condition that would result from drowning is absent, but the condition resulting in death from poison is present, and no other cause that could produce death appears. Therefore, he may say it was a case of death by poison. Perhaps even in such case it would be more correct to limit the expert testimony to a statement of the scientific facts, leaving the inevitable conclusion to be drawn by the jury. But when after the scientific facts are proven there is but one conclusion to be drawn, it is not harmful error to allow the witness to state his conclusion. But such is very different from the case at bar, where the witnesses said that many causes produced a like result, and they did not say that one was even more probable than another.

Then the defendant contended that, if the plaintiff suffered the fall she claimed she did, it was her duty to have exercised reasonable care in seeking medical or surgical aid, and that, if she neglected to do so and thereby her injury was aggravated, she was not entitled to recover for the aggravated injury. The court says that this was a correct proposition of law. The law on this subject is treated by the law writers under the head of contributory negligence, and the distinction is drawn between contributory negligence which defeats the action, which is negligence which contributes to the happening of the accident, and contributory negligence which occurs after the accident, but which increases the suffering. In either case, before the action can be defeated or the measure of damages curtailed, the plaintiff must be shown to have been guilty of negligence which contributed to the result. The law did not in this case unconditionally demand of the plaintiff that she obtain surgical aid, or charge on her the consequences of failure to obtain it, because that might have been beyond her power. But it demanded that she use reasonable care to obtain such aid, and it withheld from her the right to recover for what she may have suffered in consequence of her failure to use reasonable care. She did not seek medical aid until thirteen months had passed, and her physicians testified that the probable effect of failure to obtain such aid was an aggravation of the affliction. The reason she gave for her failure to call a physician was that she had no means to pay him, and that she did not apply to the defendant company in the trouble because she hoped all the while she would get better. Whether that was sufficient to acquit her of negligence was a question for the jury.

Practicing Without License—Statute Construed.

The Supreme Court of Minnesota holds, in the case of State vs. Orelson, that section 7896 of the General Statutes of Minnesota of 1894, imposing a fine or imprisonment, or both, on anyone practicing medicine without a license, is to be liberally construed, so as reasonably to effectuate its purpose, to

prevent frauds, and to conserve the public health. That an unlicensed person has practiced medicine is the gist of the misdemeanor, and not a gratuitous incident to it. That such person has for a fee prescribed any drug, medicine, or other agency for the treatment of disease is one kind of evidence of guilt, and not the exclusive substance of the offense. The mere fact of graduation from a medical college does not entitle to practice medicine in Minnesota. The offense defined by statute may be committed by a graduate of a medical college, as well as by any other person not licensed to practice medicine, who is not shown to be a medical student practicing under the direction of a preceptor, or not then and there being a physician or surgeon of the United States Army or Navy.

The definition of practicing medicine given on the trial of this case was in accordance with the statute, as follows: "Any person shall be regarded as practicing medicine within the meaning of this act, who shall append the letters 'M.D.' or 'M.B.' to his or her name, or for a fee prescribe, direct or recommend for the use of any person any drug or medicine or other agency for the treatment, cure or relief of any wound, fracture or bodily injury, infirmity or disease; and there is a provision that this shall not apply to dentistry." The act, the court says, is a beneficial one, and is entitled to a liberal construction. Its purpose was not, as the counsel for the defendant insisted, to merely make prescribing for a fee the offense; so that the defendant could have practiced medicine generally, could have held himself out to the world as a physician and surgeon, could have examined patients, and inferentially could have operated on them as a surgeon for pay, and yet would not have been guilty of a misdemeanor within the meaning of the act. On the contrary, its plain object was to prevent the public wrong of practicing medicine without a license.

The act, the court continues, was not enacted for the benefit of any profession or of any school or theory of medicine. It was designed to secure the public in whole and in every part from quacks, humbugs, and charlatans masquerading under the venerable and honorable titles of surgeons, physicians and doctors, and to protect the public in a just reliance on the one using these titles as a man of proper education and sufficiently trained in the sciences involved. A just enforcement of that act would tend to prevent the most deplorable swindling of the ignorant poor, who can least afford to pay for the luxury of deception, and who are the most likely to be the dupes of ostensible practitioners, whose competency has not been determined by law, and whose moral deficiencies are evidenced by their false pretenses. Its terms should be construed, so far as reasonably may be, so as to tend to eliminate the suffering of an individual from the misuse of inert drugs when potent ones are needed, and of powerful agencies productive of ill where proper ones might bring relief or effect a cure, so as to avoid many evils of malpractice, and so as to minimize the exposure of the community at large to the spread of avoidable pestilence. The act is at once a statute of frauds and a health ordinance.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

- 1 *Readjustment of Education and Research in Hygiene and Sanitation. W. T. Sedgwick, Boston.
- 2 Problem of Psychiatry in the Functional Psychoses. E. Cowles, Boston.
- 3 *Observations on Albumos in Urine. W. P. Elmer, St. Louis, Mo.
- 4 Röntgen Rays in External Treatment. M. B. Huetichus, Atlanta, Ga.
- 5 *Influence on Native Population of the Event of the Tuberculous. C. F. Gardiner, Colorado Springs, Colo.

1. Hygiene and Sanitation.—Sedgwick would have sanitation mean the care of the environment (streets, water, milk supplies, sewerage, etc.), and hygiene chiefly the care of the persons or groups of persons (feeding, vaccination, personal hygiene, etc.). The latter would then belong largely to medical men or physiologists, the former to sanitary biologists, chem-

ists and engineers. He laments the small attention paid to hygiene and sanitation, alike in medical schools and in schools of engineering, and looks for a remedy partly in the better definition and separation of these subjects, and partly in the establishment of permanent well-paid positions for trained men in the public health service—which should at the same time be made more general and less local. Sedgwick concludes his paper as follows: Politics must also be wholly eliminated from our boards of health, both state and municipal. There is no republican method of vaccination, no democratic plan of street cleaning. Places on boards of health must not be used as rewards of political activity. The time—if it ever existed—has gone by when a good board of health can be made up of a political doctor, a political saloon-keeper and a political nobody; for no well-trained and self-respecting expert in hygiene or sanitation can or will remain in the dubious and uncertain service of weak, incompetent or shifty characters.

3. Albumoses in Urine.—Elmer mentions the following as the diseases in which albumosuria occurs most frequently. Multiple myeloma of bones, tuberculosis, especially pulmonary, croupous pneumonia in the stage of resolution, septicemia, pyemia, abscess, carcinoma and sarcoma when undergoing rapid retrograde changes, and the leukemias and Hodgkin's disease after treatment with Roentgen rays. He recommends the following test for albumose as being the most practical: The reagent consists of a 50 per cent. solution of sulphosalicylic acid in distilled water. This reagent precipitates on contact all proteins found in the urine, but the albumoses redissolve on warming the urine, while albumins, globulins, etc., do not, so that when any or all of the albumin group are present with albumoses filtered the warmed urine will separate them, and the albumoses be determined by cooling the filtrate. Care must be taken to avoid prolonged boiling, for if mucins be present they may be broken down, one of the products being an albumose. A very small quantity of albumoses may be detected by dividing the urine after adding the reagent and warming one part while cooling the other and comparing the tubes before a dark surface.

5. Event of Tuberculous on Native Population.—Gardiner claims to have made a thorough study of this question and states that his records show that the natives of open resorts for the tuberculous are in a better physiologic condition to resist tuberculous infection than the average inhabitants of other towns and cities. All the facts seem to prove that it is better to be exposed daily for years to the germs from the tuberculous in a superior climate than not to be so frequently exposed, but to be under the influence of bad air and overcrowding in an unfavorable climate. The event of the tuberculous among the dwellers in our resorts is not so dangerous a factor as it has been supposed to be. The lesson to be drawn from this is to increase human resistance by proper ventilation day and night, for then the tubercle bacillus will lose its power to infect mankind or to destroy life.

6. Sanitary Importance of Clean Milk. C. Harrington, Boston.
7. Results of Operation for the Removal of Cerebral Tumors. P. C. Knapp, Boston.

8. Two Cases of Erythema Multiforme Desquamativum. P. K. Brown, San Francisco.

8. Erythema Multiforme Desquamativum.—The two cases reported by Brown are interesting for several reasons. One of the patients had gastrointestinal crises, fever, joint, heart and kidney complications. The other had intestinal disturbances, fever, slight kidney disturbance, angioneurotic edema and purpura with hemorrhages from the mucous membranes. Digestive manifestations preceded all the attacks in one case and preceded the single attack in the other. For ten days the first patient suffered from epigastric pain, cramp-like in character. When first seen there was a diffuse, tiny, regular eruption all over the trunk, shoulders and thighs, which had not appeared on the face, neck, arms or legs. It was perfectly discrete. It had no crescentic appearance and consisted of tiny reddened areas, slightly raised in the center, each one about the size of a pinhead. There was no pain anywhere. There had been

slight throat symptoms forty-eight hours before, but there was no eruption on the cheeks or throat, and no coryza or eye symptoms. The glands were slightly enlarged everywhere. There was no evidence of any skin infection. Temperature was 99.5 the following day, and the eruption had covered the entire body and the face except about the mouth. Where the itching had caused the patient to scratch it a good deal, it was diffusely red between the patches, looking more like scarlet fever. There was a shotty feel to the eruption on the trunk and extremities. The palms and soles were also affected. Desquamation was complete six weeks after the attack was over. The second case was diagnosed at first as one of German measles. There was no eruption on the face at all, but marked pallor. The papillae on the tongue were prominent and the tongue itself coated. The tonsils were slightly large and red, but there was no membrane. There was no tenderness behind the ears, but the glands in the neck were slightly enlarged. The axillary and inguinal glands were tender and markedly enlarged, some of them being as large as very large beans. There was some swelling of the tissue under the angle of the right side of the jaw. There were some mottled red blotches, one nearly 1 cm. broad, on both ears. Over the chest and particularly over the back there was a slightly mottled but diffuse blush. It was particularly marked over the neck and buttocks, around the genital organs and slightly down the inner side of the thighs. Toward the extremities it became much more mottled, certain of the blotches being quite discrete. On the dependent parts the pressure of the clothes in folds had caused linear ecchymoses, looking very much like long scratches, particularly marked over the buttocks and shoulders. There was a marked absence of eruption or blush in the axillary spaces. This patient had several such attacks, in the last of which the eruption was distinctly purpuric.

9. Medical Treatment of Nephritis.—In this paper Tyson repeats the statements made by him in previous papers.

10. Hereditary Syphilis.—Taylor attempts to prove, by cases, that third infection in syphilis is an established fact. A synopsis of the first case is as follows: First.—Grandmother infected with syphilis in 1869, had secondary and tertiary lesions of much severity. She was careless of treatment. She was the first genitor. Second.—In 1872 this woman gave birth to a girl baby which presented classical hereditary syphilitic symptoms. After many vicissitudes this child (the second genitor) grew up seemingly healthy and strong, and never having been infected with acquired syphilis, she in two years gave birth to a baby daughter. Third.—In 1890 this second genitor gave birth to a miserable weakling girl, atrophic, marasmic, with very little strength and vitality, who at birth gave no distinct evidence of hereditary syphilis (third generation), but who in five years developed true dystrophic symptoms; Hutchinson's teeth, keratitis, ear troubles, and osseous swellings, and later showed unmistakable evidence of a virulent form of late syphilitic infection (third) in characteristic gummatous tumors and ulcers. This third syphilitic by inheritance is now growing up a victim of infantilism and general atrophy. A synopsis of the second case is as follows: First.—A healthy woman, married to a man, syphilitic two years, contracted syphilis two years later coincidently with the development of pregnancy. Second.—She gave birth to a male child who, soon after birth, was characteristically heredito-syphilitic and later developed typical undoubted evidences of inherited taint, which showed themselves for several years. He never was infected with acquired syphilis. He married a healthy girl. Third.—Three years after the marriage of this second genitor, the wife gave birth to a thin, weakly girl, who

presented the appearances of infantilism. At 4 years many dystrophic symptoms of the bones and joints developed and were promptly cured by active antisyphilitic treatment. This case, therefore, was a clearly marked illustration of the development of syphilis in three generations. In the first, active syphilis; in the second, virulent hereditary syphilis; and, in the third, a dyscrasic condition attended with well-marked dystrophic changes.

15. **Gonococcus Vaginitis.**—Trendelenburg emphasizes the following points: 1. The great need for early diagnosis and treatment. 2. The necessity for frequent douching with large quantities of the solution. 3. The use of absorbent cotton as a dressing for the parts. 4. The need for care and gentleness in the treatment. 5. That a case should not be considered as cured until not only the discharge has stopped, but until it is no longer possible to find the gonococci in the vaginal secretions microscopically. 6. The need of impressing the mother with the serious nature of the disease and the necessity for treatment until the gonococci have entirely disappeared. 7. The greater dissemination of knowledge among men and women who suffer from gonorrhea, as to its infectiousness to others, and its power to do, at times, great harm, at a period remote from the time of primary infection when the disease remains uncured. 8. The great necessity for care in keeping cases of gonococcus vaginitis out of day nurseries and babies' hospitals, because of the epidemic character which it assumes among the inmates once it has gained a foothold.

16. **Tuberculosis of the Appendix.**—The diagnosis of Hanbold's case was confirmed microscopically. No tuberculous foci were noted in the peritoneum and a careful examination of the lungs did not reveal any indication of pulmonary tuberculosis. There was no cough and no expectoration. The patient died about nine weeks after the operation.

21. "Two Cases of Pseudoleukemic Anemia of Infancy." E. M. Sill, New York.
22. Air de Luxe. W. P. Northrup, New York.

17. **Clean Air.**—Prudden says that it is interesting to note from the careful experiments which have been made that ordinary ventilation, however effective it may be in supplying fresh air and in removing contaminated gases, has no noteworthy effect in the removal of dust, either floating or at rest. Experiments also prove that hanging garments out of doors merely, is not to be commended. Unless such articles are brushed, or beaten, or shaken, or unless they flap violently in the wind, bacteria are not removed in great numbers. The writer emphasizes the fact that a large part of so-called disinfection might be replaced to advantage with proper methods of sweeping, dusting and mopping, if all these were not so simple and commonplace, and if everyone could realize the significance of dust in the conveyance of infectious agents. He emphasizes the importance of the use of moist mops on the floors, and of moist dust cloths on the solid furniture. He denounces the employment of the feather duster. The sprinkling of damp sawdust on floors before sweeping is a great aid in getting rid of much dust. He declares that the infectious diseases of the respiratory organs are steadily increasing as people are more and more huddled together in offices, dwellings, traveling conveyances and places of public assemblage. A large number of these diseases are directly traceable to infectious material passed off in spitting, coughing and sneezing, by those suffering from various degrees of local disease. Promiscuous spitting should be stopped. The harmfulness of coughing and sneezing can in most instances be controlled by the use of the handkerchief.

18. **What Constitutes Pneumonia?**—Smith contends that a single pneumococcus lodged in an air cell and causing there its specific irritation and consequent exudation, presents all the essentials of the disease. He declares that it matters not if ten minutes later the organism is dislodged and swept away by the exudate, the patient even then has had a pneumonia, if

only a monococcal one. If later the bronchiole terminating in the lobule invaded becomes blocked, and the further spread of the infection is prevented, the patient may escape with a unilobular pneumonia, but it will be pneumonia nevertheless. Smith believes that such abortive attacks are very common.

19. **Danger and Protection in X-Ray Work.**—Lehmann emphasizes the necessity for shielding the operator not only from the Roentgen rays, but from the secondary rays as well. He says that the best means of protection is a gown of impermeable material. Complete suits have been made of material of different degrees of safety, the heavier and bulkier the better, and sheet lead is the only safe thing. In a suit of this sort described by the author, the apron of Roentgen-proof material reached from the neck to the knees; the cap covered the face and head and was provided with lead glasses. The gloves were also ray-proof, but neat enough to permit of handling screen and apparatus.

21. **Pseudoleukemic Anemia of Infancy.**—Sill reports two cases. One of his patients died six weeks after he was called in; the other is still alive after five months and is steadily improving. The treatment has been proper diet, cod-liver oil and Fowler's solution.

23. **Appendicitis Complicated with Typhoid.**—When first seen, Avery's patient was suffering acute pain in the abdomen. This pain was most intense over the hypochondrium, but the entire abdomen was tender to the touch, with severe local tenderness over McBurney's point. The right rectus was rigid; the patient was nauseated at times, had some headache, and was constipated. The temperature varied between 101 and 103.5 F. In spite of all medication the bowels did not move until about the fifth or sixth day. About the seventh day a slight wave made its appearance in the temperature chart, an evening rise and a morning fall. Rose-colored spots appeared on the abdomen three or four days later. The stools at this time were characteristic of typhoid. The disease ran the usual course and the patient made a complete recovery. A laparotomy was then done and the appendix was found completely wrapped up by the omentum to which it had become adherent, and showed distinct signs of recent inflammation.

24. **Wright's Opsonic Index.**—Attention is drawn by Clemens to the advantages of Wright's method as a means for diagnosing tuberculosis. He considers it harmless and practically infallible. It is especially valuable because the diagnosis is made outside the patient's body; it permits of the use of tuberculin to the patient's best advantage—curative; it removes the dangers of diagnosis by tuberculin.

27. **Light and Skin Cancer.**—According to Hyde, the skin of the human body, in a certain proportion of individuals, and in those only, is hypersensitive to the action of the actinic rays of the spectrum. This hypersensitiveness may be exhibited in the production of either hyperemia, pigmentation, telangiectasis, atrophy, hyperkeratosis or cancerosis of the skin; or by all, and at times in a determined order of succession. In the form of childhood cancerosis known as xeroderma pigmentosum, the pigmentation, telangiectasis, atrophy, hyperkeratosis, and cancerosis of the skin resulting from exposure to rays of light are exhibited early in life, instances of this disorder being exceedingly rare. Pigmentation, telangiectasis, atrophy, hyperkeratosis, and cancerosis of the skin occur in adults much more frequently than in childhood, reaction to the play of actinic rays of light on the surface being chiefly determined after the middle periods of life have been reached. Physiologic pigmentation of the skin in the colored races seems to furnish immunity against cancerosis of that organ. The colored races apparently suffer less than the whites from cancer of other organs than the skin. This relative immunity may be due to the protection from actinic rays of light furnished by the pigment of the integument.

28. **New Operation for Dupuytren's Contraction.**—Keen refers to a case of Dupuytren's contraction of the palmar fascia in which he performed a new operation, the parts being anesthetized by neural infiltration. He first infiltrated the skin just above the wrist, over the median and the ulnar nerves, with a solution of beta-eucain and adrenalin, of which the following is the formula:

R. Sol. adrenalin chlorid.	3iiss	10j
Beta-eucain	3ss	2j
Sodii chlorid	3iii	8j
Aque dest. q. s. ad	3vii	210j

Having exposed these two nerves he then injected a few drops of this same solution into them. After waiting for a considerable time he attempted to begin the operation, but found that it was exceedingly painful. Scarcely any diminution of sensation had been produced by the infiltration, although the injection at the site of the operation on the two nerves had been entirely satisfactory. He then injected into each nerve four or five drops of a 4 per cent. solution of cocaine, and within three minutes was able to begin the operation without causing the slightest pain. In consequence of the very careful dissection in the palm, the operation lasted over half an hour. The local anesthesia at its end was quite as satisfactory as at the beginning. He began the incision at the ball of the thumb on a line with the interspace between the forefinger and middle finger, went down almost to the web between the forefinger and middle finger, then transversely to a point corresponding to the beginning of the incision on the other side of the hand. The dissection of the flap was begun at the transverse incision corresponding to the knuckles and went directly down to the sheaths of the tendons. He dissected back the entire flap, including on the under surface of the flap the entire palmar fascia. He then dissected away the palmar fascia from the under surface of the flap, the fingers of the assistant being on the palmar surface of the skin, so as to warn him if he got too close to the skin. In order to dissect out the fibers going to the index and the little fingers, he next undermined the skin overlying them, and was able to get at the beginning small bands of fibrous tissue which had not been turned back in the large flap. He tied half a dozen small vessels with catgut, so as to have as little danger from any effused blood as possible. Union took place by first intention throughout both of the small operation wounds over the nerves and that in the palm of the hand. No sloughing whatever took place; even a little nick that he made inadvertently in the skin of the palm was rather advantageous, as it allowed what little blood was effused under the flap to escape. The patient was discharged from the hospital with almost normal motion of the fingers.

31. **Opium in Heart Disease.**—According to Musser, there are sound clinical reasons for the belief that opium is a tonic in cardiac debility. He says that in cases of weak heart after exhausting disease, after prolonged mental and physical

pain, and without organic lesion of valves or muscle, opium is of advantage. In cases of failing compensation, with the onset of stasis, the heart is supported, especially if the unfortunate possessor is an impressionable subject who frets and fumes because of the ordinary irritations of life. In the gradual "engorgements from myocardial dilatation, in chronic parenchymatous nephritis, and in arteriosclerosis it is of value. If the patient is hypochondriacal or hypersensitive the second daily dose of opium invites sleep and induces a feeling of well-being. The dyspnea of myocarditis is relieved or prevented by continuous small doses of morphin for a very long time. Musser has seen a form or stage of myocarditis with restlessness, Cheyne-Stokes breathing, dyspnea and rapid pulse helped by continuous doses of opium. The tachycardia of Graves' disease is relieved and in three of his cases it appeared to contribute to the cure of the disease. In nervous and irritable patients opium is almost necessary to induce comfort.

34. **Rheumatism of Stomach.**—Halloway cites the case of a man, aged 67, of abstemious habits, who was troubled with dyspepsia for thirty years. He suffered from attacks of pain in his stomach, which usually came on about the fall of the year and continued, off and on, throughout the whole winter. He always felt well during the summer heat. The diagnosis was dyspepsia, and various dietary regimens and many medicines were prescribed, but the result was always a negative one. For a year past he suffered severely from cramps, coming on mostly in the night, and becoming more severe when the weather was about to change. After a careful study of the symptoms of this case and the results obtained from climatic treatment, Halloway is convinced that it was a case of rheumatism of the stomach.

35. **Anthraxis Simulating Thoracic Aneurism.**—Sewall's patient suffered from a mild degree of pulmonary tuberculosis. Besides this there could be heard a systolic bruit confined to an area represented by the lower half of the right scapula. This bruit was suspected to arise from a thoracic aneurism. The patient felt quite well except for some shortness of breath. After a six months' stay in bed she coughed up some bright blood and complained of intense pain over her heart, greatly aggravated by inspiration. These events were taken as evidence that an aneurism had ruptured by the section, the blood probably penetrating the pericardial cavity. Death ensued after twenty-four hours. At the autopsy no sign of aneurism was found. At the root of the right lung there was a hard, solid mass, pyriform in shape, four inches long, over three inches wide and two and a half inches deep. This mass, on section, was found to be black in color and gristly in resistance. At the root of the left lung, immediately posterior to the left bronchus, was a similar mass consisting of two portions. Numerous small black bodies, the size of grains of wheat, were scattered throughout the lung. An extraordinary degree of emphysema involved the margins of the lung. On chemical examination the pigmented masses were found to be coal dust. Hyperplasia of connective tissue also was present in the masses, and Sewall is of the opinion that this was due to the irritation of the coal dust, a true anthracosis.

40. **Spirochete in Syphilis.**—During the past four months Rosenberg has made studies of chancres, mucous patches, enlarged glands, condylomas, eruptions and cerebrospinal fluid with a view to finding the spirochete and establishing its causative relationship to syphilis. In every specimen examined, with the exception of the cerebrospinal fluid, the *Spirocheta pallida* was demonstrable.

41. **Floating Kidney.**—According to Longyear, the usual operation of nephropexy is inadequate because it fails to meet all the indications in the conditions present. To be effective the operation must certainly do one thing which the stitching of the stripped kidney, only, to the loin, can not accomplish, viz., the prevention of the descent of the ascending colon and cecum. The operation must have for its aim the attachment of both kidney and bowel; or the nephrocolic attachment may be severed—thus preventing traction on the kidney and duodenum—and the kidney fixed by simply stitching the

severed ligament into the wound at its appendage. The operation which Longyear has found the most easy of accomplishment, and which seems to meet the two indications mentioned, is the fixation of the nephrocolic ligament into the upper angle of the wound without severing it from the colon, and also fastening any redundant mesentery that may be present in the lower angle of the wound. The convergence of the framework of the fatty capsule into this ligament makes a structure of sufficient strength to be depended on to hold the displaced organs, if securely attached to the aponeurotic tissue, preferably where it is thick near the twelfth rib. The kidney fixed by this ligament is placed at nearly its normal position and is not held in an immovable position, as is the case when united to the muscles by the usual operation. The bowel is also held by the same attachment and undue descent of the cecum prevented, and it is possible that this will prove sufficient, but at present the writer deems the shortening of a redundant mesentery best, if for no other reason than that it will prevent traction on the other attachment while it is becoming firmly fixed. The opening into the peritoneal cavity has the added advantage of giving free access to the kidney and enabling the operator to handle the organ at will, through its close attachment to the colon, traction on the latter, brought through the wound, serving to bring the kidney close to the opening. Longyear says that the difficulty of handling the kidney when grasped by the sides of the fatty capsule has been experienced by all, as the tissue gives way readily and appears to have little resisting power. This is because the fine fibers forming the network of this capsule are spread out and the trabeculae widely separated by the fat deposited between them. As they converge below the lower pole of the kidney to become inserted into the posterior wall of the bowel, they lie parallel to each other, and by their aggregation form a strong band of a good deal of resisting power, so that the kidney can be readily held in firm fixation by means of a blunt hook passed around it, permitting complete control of the organ for examination or farther operation.

48. Medical Supply Table for National Guard.—Stanton has prepared a list of fifty-four medicines which he believes contains all the medical supplies absolutely essential for an ordinary tour of duty of a regiment of the national guard. No quantities are specified, as it is intended that the state shall keep these supplies in store, and that requisitions shall be made from day to day as occasion may demand. This medical supply table has been adopted as the official supply table for the use of the Illinois National Guard and Naval Reserve. Included in this list are acetanilid compound, boric acid, borosalicylic acid, salicylic acid, alcohol, alum, ammonium bromid, aromatic spirits of ammonia, amyl nitrite, bismuth subgallate, compound tincture of benzoin, chloroform, antiseptic bicliohol tablets, iodine, calomel, magnesium sulphate, morphine, Dover's powder, nitroglycerin, castor oil, pedonizing tablets, petrolatum-pissum, aloin compound pills.

53. Surgery of Pelvic Floor.—Jewett summarizes his paper as follows: The pelvic floor is essentially a muscular diaphragm. The muscles of the floor are disposed in two distinct layers. These layers are separated by the plane of the hymen. The upper layer is the levator ani. The general trend of the levator fibers is toward the coccyx. The rectum and the perineal body are in relation with the median borders of the levator muscles. The tubular viscera are slung in the pelvis mainly by the levator attachments to the rectum and to the bridge of fibrous elements in the perineal body. The most essential part of the obstetric injury is the rupture of these fascial attachments behind the vaginal sulcus and alongside the rectum. The reparative operation should be addressed, in the main, to the restoration of these fascial attachments. Jewett believes that restoration *ad integrum* is best effected by the technic of Emmet, and that Holden's operation is the simplest and most definite of the procedures yet devised which attempts support by substituting an artificial for the natural relations of the pubic bands of the levator muscles.

62. Insanity a Symptom of Old Fracture of Skull; Operation; Recovery. J. E. Chambers, St. Louis.

61. Inguinal Hernia.—For the radical cure of inguinal hernia Butler employs a modification of Halstead's operation: A skin incision is made parallel to Poupart's ligament and three-fourths of an inch internal to it, extending from a point slightly beyond the internal abdominal ring to the spine of the pubes. The subcutaneous tissues are divided in their turn the full length of the skin incision. The external oblique is first incised parallel to the direction of its own fibers, then the internal oblique and transversalis are cut, and finally the transversalis fascia having been divided, the spermatic canal is fully exposed from the internal to the external abdominal ring, thus bringing into view the cord. The vas deferens is isolated and if there is any tendency to enlargement of its accompanying veins all but two or three are ligated, above and below, and dissected out. The subcutaneous incision is extended five-eighths of an inch or more beyond the internal ring, in order to release the constriction and to get firm, fresh tissue from which to build the new exit for the cord. Following this the sac is opened, its contents carefully examined and replaced within the abdomen. A ligature of catgut is now passed around the neck of the sac close to the internal ring and the sac is cut away. The ends of the ligature which have been left long are threaded separately through long curved needles, passed eye-end first through the abdominal opening alongside of the stump of the sac and brought out a quarter of an inch apart through the internal oblique at a point one and one-half inches internal to the upper angle of the incision, where gentle traction is made to draw the stump of the sac away from the field of operation, when, by tying the ligature, the stump is held in a permanently displaced position. Any cicatricial mass or tissue of questionable vitality is dissected away from about the old internal abdominal ring. Each muscular layer is sutured separately, allowing the edges to overlap as much as the tension will allow, until the external oblique is reached. Instead of suturing the aponeurosis of the external oblique in a direct line, as in case of the other layers, a strip of one-half inch wide and one and one-half inches long is cut from the internal border of the external oblique at a point directly opposite the site of the new ring, leaving the upper end of the strip fast and passing the loose end under the cord and suturing it to the superior surface of Poupart's ligament. This gives a firm ring with the fibers running crosswise to the direction of greatest strain. The remainder of the aponeurosis is sutured behind this loop in the same manner as the underlying structures, using silk or fine silver wire. Butler says that this portion of the method was employed by

the late W. V. Morgan of Indianapolis, for two years prior to his death and since that time by himself, together in more than fifty cases, with uniformly good results. The hernia now having been reduced, the stump of sac displaced, away from the operative field, the cord located on its new bed and the hernial opening obliterated, all that remains to be done is to suture the skin firmly with kangaroo tendon and to apply a dry dressing.

2. Significance of Sugar and Albumin in Urine.—Burnett thinks that it may be said that the presence of albumin in any appreciable amount in the urine is not normal nor physiologic, but that it does not necessarily imply coarse pathologic change, and that it does not necessarily mean that the existing disturbance of function is permanent or progressive. At the same time, it can not be denied that a certain number of patients who at first are rightly placed in the above category do later show signs of definite organic kidney disease. The presence of sugar in the urine in any appreciable quantity is abnormal; in the young it is of serious import, and, if persistent, is likely to lead to diabetes; in people past middle life, and especially in those of gouty type, it is of less consequence and usually yields to treatment more or less speedily, to recur,

however, in some cases, under conditions similar to those under which it first appeared. The presence of both albumin and of sugar in the urine indicates serious disturbance in the metabolic processes, calling for relief to the nervous strain which the patient may have been undergoing, and an adjustment as far as can be of his environment, but Burnett thinks that under favorable conditions these patients may continue in at least fair average health for many years.

4. **Chemiotaxis.**—Barratt summarizes his observations as follows:

1. Paramoecia pass readily into tubes containing acid and alkaline solutions of sublethal concentration, but pass still more readily into control tubes containing the same liquid as that in which the paramoecia are immersed.

2. Only negative chemotaxis appears to be exerted by acids and alkalies on paramoecia. This negative chemotaxis is marked in alkaline solutions of lethal concentration, and is slighter in acid solutions of lethal concentration.

3. There is no parallelism between (a) the lethal concentration of acids and alkalies for paramoecia, and (b) the chemotaxis of paramoecia in respect of acids and alkalies.

4. The taxis of paramoecia is modified when these organisms are transferred from hay infusion to distilled water.

5. Chemotaxis is to be explained simply by reference to the acidity or alkalinity of the solutions employed. Mere change of concentration is an important factor in its production.

6. Negative chemotaxis does not necessarily indicate that the liquid tested acts injuriously on the organisms employed.

7. **Action of Trypsin on Living Cells.**—Beard tested the action of trypsin on the living cells of a Jensen's mouse-tumor. Two minims of a 1.5 per cent. solution of trypsin in sterilized distilled water were injected on four different occasions in the course of ten days. One of the mice was then found dead and a postmortem examination failed to reveal any cause of death. The microscopic examination demonstrated that every cell of the tumor was degenerated, fully half of the cells being represented by shapeless masses of particles, probably the remains of nuclei, and all the rest were mere skeletons of cells. The somatic tissues of the mouth, as represented by the leucocytes and connective tissue cells, were quite normal. The second mouse received nine injections in twenty-two days. The mouse was then killed and the tumor was exposed. The growth was about the size of a lentil and the cells were all degenerated. Beard believes that at the time this mouse was killed its cure from the cancer was not far distant, and that even without further treatment the tumor would in all probability have been absorbed shortly. A control mouse died at the same time that the second mouse was killed. The tumor in this control mouse was as large as the terminal phalanx of a man's thumb. Beard says that no matter how often this experiment is repeated, even with smaller doses of trypsin, the like results will be obtained. He is convinced that the action of trypsin on the cancer cell is to pull down the cancer albumin and the cancer ferment (malignin) produced by this.

9. **Bradycardia and Cardiac Arrhythmia.**—Hay reports a case of bradycardia due to heart block. When the patient was first seen the block was caused by depression of conductivity; later the conductivity became practically normal and the block which persisted was found to be caused by depression of excitability. Atropin increased the frequency of the stimulus production, but had no influence on the power of conductivity. Sounds were heard during the diastolic phase of the ventricles; they were synchronous with the wave in the jugular vein caused by the systole of the right auricle. Hay thinks the assumption justifiable that the sounds were produced by the auricle in its systole, and that the depression of the conductivity and excitability of the myocardium was probably due to impaired metabolism, secondary to an insufficient blood supply, the result of arteriosclerotic changes in the coronary arteries. The excitability of the musculature was unstable,

possibly as a result of nervous influences such as mental excitement.

10. **Calcium Salts as a Headache Cure.**—Ross believes that we have in the salts of calcium a rational and effectual means of relieving headaches which are due to a deficient coagulability of the blood. He prefers the lactate of calcium to the chlorid because the latter is unpalatable, often nauseating, and occasionally not absorbed. The following has proved a satisfactory mixture:

Calcium lactatis.....	gr. xv	1
Tinct. capsici.....	m. ½	033
Aque chloroformi.....	3i	30

Sig.: To be taken three times a day before noon.

If more convenient, fifteen grains of lactate of calcium dissolved in one-third of a tumbler of water may be given in place of the mixture. If the lactate of calcium is not obtainable, fifteen grains of the chlorid and one ounce of camphor water may be substituted. The ingestion of one or two pints of milk a day is advisable though not essential. Ross says that in a number of cases, usually of the less severe type, considerable relief is felt in from half to one and a half hour after the administration of the calcium salt. In others the relief comes during the first twenty-four hours of treatment, while in almost all the cases the headaches disappear after the fourth day. He reiterates that it is advisable to continue the administration of calcium for three weeks in the milder type of headaches, and for six weeks in the more severe types. Ross has treated 48 patients according to this method.

12. **Primary Pneumococcus Peritonitis.**—Ashdowne reports a case of acute peritonitis due to a primary infection by the diplococcus pneumoniae. With the exception of pain after meals for the past six months she had been quite well until fourteen days previously, when she was seized with abdominal pain, accompanied by diarrhea and vomiting. This she attributed to an error of diet and took some brandy, which relieved the pain. She remained in bed for two days, taking no solid food, and on the third day had recovered sufficiently to resume her household duties. Two days before admission to the hospital she was again seized with acute abdominal pain and diarrhea; she felt sick but did not vomit. She again treated herself, but as the symptoms continued on the following day she consulted her medical man, who gave her medicine which stopped the pain and diarrhea for the time. In the evening the pain returned and the abdomen commenced to swell. The abdomen was distended, more so above the umbilicus than below it. Movement was impaired, but there was no muscular rigidity. There was some tenderness over the right iliac region, but no evidence of a tumor. The abdomen was resonant except over the hypogastrium. Liver dullness was present. Rectal examination revealed nothing abnormal. The patient's menstrual periods were regular and one was then in progress. The heart and lungs were normal. Her temperature was 103.6 F., the pulse was 128, and the respirations were 32. The distension was most marked in the upper part of the abdomen and there was tenderness on pressure in this region, but the lower segment was less distended and there was no tenderness. The iliac fossae were quite free from swelling or tenderness. On opening the abdomen in the middle line above the umbilicus, the stomach, which was greatly distended, presented. A quantity of pus was found between the stomach and the liver with thick fibrinous deposits on the surface of the viscera in the vicinity. The pus was odorless, creamy, and of a greenish-yellow color, with numerous flocculi floating in it. Some of this was collected and set aside for bacteriologic examination. The fibrinous deposits adhered to that membrane was seen to be lusterless, reddened, and in places inclined to bleed. No lesion of the stomach, duodenum or gall bladder could be found. A second opening was made below the umbilicus and a similar condition was found there. The appendix, intestines and uterine appendages were each in turn examined, but without finding anything to account for the onset of the condition. The peritoneal cavity was then sponged out and well flushed with sterilized water. A Keith's tube was placed in the pelvis and the rest of the incisions were closed. The patient recovered from the anesthetic, but in the evening be-

came very restless and later delirious, and died early the following morning. The pus removed at the time of the operation contained encapsulated diplococci and a pure culture of diplococci was obtained from it. There were no other organisms present.

21. **Lithiasis of the Common Bile Duct.**—Chauffard gives an illustration of a calculus weighing 9 gm. (nearly 140 grains) extracted from the common bile duct of a man of 48; there was no trace of inflammation or disturbance in the other biliary passages. He has also had occasion to observe a second case of pure lithiasis of the common bile duct, and discusses the symptomatology, which is characteristic. Both his patients were permanently cured by surgical removal of the stone. In 50 out of the 72 cases on record the calculus was a large single stone, forming a cast of the dilated duct. The one illustrated was two inches long by more than three-fourths of an inch in width. It develops like thrombosis in a vein, suggesting, he says, "an actual cholecholeal biliary thrombosis." When the obstruction from the stone induces expulsive colic and fever from retention of bile, the pancreas is liable to become inflamed in turn. It reacts with progressive sclerosis or more acute lesions. Chauffard urges the necessity for diagnosing these cases of lithiasis of the bile duct before it reaches this stage. Prompt removal of the stone without wasting time in medical measures will save the patient these disturbances and dangers. The icterus in his two cases was very slight and intermittent, and the stools were only occasionally clay-colored. These fluctuations are due to the conditions of the walls of the duct. If they are swollen with inflammation there is more or less complete obstruction, but when they are not inflamed they stretch and allow bile to trickle through. The pain is not characteristic, but localized tenderness in what he calls the "pancreas-cholecholeus zone" may be instructive. This zone is the space between a line perpendicular to the umbilicus and a second line drawn from the umbilicus at an angle of 45 degrees to the first line. The zone in this angle does not reach quite to the umbilicus below and does not extend for more than 2 cm. along the slanting line. Experiments on the cadaver have shown that this zone corresponds to the head of the pancreas, traversed or skirted by the bile duct. The gall bladder is above and to the right, the distance between the gall bladder region and the zone being the length of the bile duct. Systematic exploration of this zone will generally reveal a point of extreme tenderness, referable either to the bile duct or to the pancreas. The fever in case of lithiasis of the bile duct occurs in spurts of high temperature, brief but frequent, suggesting the fever of icterus, and paralleled by hyperleucocytosis. His patient had lost 36 kilos (nearly 80 pounds) in ten months, suggesting the possibility of cancer. This decline in weight is probably due to the involvement of the pancreas in the process, interfering with pancreatic digestion. Secondary pancreatitis is especially liable to occur in lithiasis of the bile duct. This involvement of the pancreas can be determined by examination of the feces, revealing the lack of utilization of the fats ingested.

24. **The Systolic Souffle of Pure Aortic Insufficiency.**—Couto's article is based on personal experience and study of what has been written on the subject in Italy, Russia, South America and elsewhere. He argues that none of the explanations to date are correct, and gives diagrams which explain his concep-

tion of the phenomenon. He regards the two souffles heard in auscultation, one presystolic and the other diastolic, as the essential characteristics of pure aortic insufficiency. The organic cause of the first of these souffles resides in the alteration itself, which prevents the perfect closure of the semilunar valves during diastole. This presystolic souffle is due to the passage of a retrograde wave from the aorta into the ventricle, through the orifice of the aorta, during the occlusive phase of the systole.

25. **Pregnancy Plus Appendicitis.**—Füh has had occasion to observe 5 cases of this kind. From this experience and from study of the literature he concludes that appendicitis is a serious complication of pregnancy, especially on account of the tendency to recurrence. Recurrence was noted in 21 per cent. of the cases recorded. Monod and others advise removal of the appendix, as a rule, even when there are no symptoms, at the third or fourth month of pregnancy if the patient has ever had appendicitis. In case of incipient appendicitis in a pregnant woman, all agree that immediate appendectomy offers the only chance of cure. An important aid in differentiating appendicitis, he states, is the great difference between the temperature in the axilla and that in the rectum. In one of Füh's patients this difference amounted to from 1.9 to 2.6 Centigrade degrees. The anatomic conditions in pregnancy favor the evacuation through the vagina of an appendicitic abscess in the Douglas pouch. If there is too much danger of interrupting the pregnancy, the abscess can be opened through the rectum.

27. **Eclampsia.**—Zweifel found crystals of zinc paracetate in the urine of 17 eclamptic women. Lactic acid is a constant constituent of the urine in eclampsia. It is probably derived from the meat ingested, and he considers it responsible for the eclampsia. Everything seems to indicate that eclampsia is an acid intoxication. Lactic acid is a product of deficient oxidation. It was found both in the blood and in the urine of his eclamptic patients. Its appearance in the blood or urine is always an indication of morbid conditions. In one of the eclamptic women a large proportion of lactic acid was found in the blood during the attacks, but five hours after the last attack there was no longer a trace of it. In some cases a larger proportion of lactic acid was found in the blood of the fetus than in the mother's blood. Zweifel regards this as an argument in favor of immediate delivery at the first signs of eclampsia. The children, as a rule, do not seem to suffer from the maternal eclampsia. None of the children with lactic acid in the blood was born dead in his experience. The bag of waters should be emptied at once and delivery carried out under chloroform. It should not be forgotten that morphin in experimental research induces the appearance of lactic acid in the urine. Venesection is indicated and saline alkaline infusion (5 gm. salt and 5 gm. sodium bicarbonate to the liter of water) to neutralize the lactic acid in the blood and favor its elimination. Lemonade with sodium or alkaline citrates is also beneficial. The stomach should be emptied before pouring in the lemonade. The tube can be introduced through the nose at need. Diuretics are also useful, 40 drops of a saturated solution of acetum scillae or the like. He thinks the trouble is due to an excessive consumption of the oxygen in the body by the demands of the growing fetus. To supply oxygen is, therefore, the main indication. The shallow respiration of eclampsia does not allow of adequate intake of oxygen, and to insure deep breathing Zweifel applied electric stimuli (faradic) to the phrenic nerves. This transformed the type of respiration and the oxygen thus abundantly inhaled seemed to have a favorable action on the eclampsia. Restriction of meat during

pregnancy might reduce the formation of lactic acid. A vegetable diet seems more rational on this account. If pregnant women had their urine examined every two weeks for albumin, nephritis might be detected earlier. Some cases of eclampsia, however, develop witho t preceding albuminuria.

29. **Treatment of Rupture of Uterus.**—Eversmann summarizes the results of his own and others' experience in the statement that tamponing, with a compressing bandage, gives the best results. This should be regarded as the standard treatment under general circumstances. If operative treatment becomes necessary, total removal of the uterus by a laparotomy with suture of the serosa offers the best chances. His statistics embrace 170 cases.

30. **Bacteriology of Female Genital Secretions.**—Natvig's monograph fills 159 pages. It presents evidence in favor of the assumption that streptococci, living as saprophytes in the vulva, are liable to make their way into the uterus and to acquire virulence under these conditions. He knows of no instance of puerperal infection from this source, although he admits its possibility.

31. **Determination of Outlines of Stomach.**—Schüle calls attention to the sources of error in determining the outlines of the stomach by inflation of the empty and percussion of the distended organ. All writers concur in stating that the normal stomach lies entirely above the umbilicus. When the stomach is distended with artificially induced gas it is forced downward, sometimes as much as 2 cm. below its normal outline when the person stands. Another source of error is when the transverse colon lies in front of the stomach. The colon is forced forward as the stomach becomes distended by the formation of gas. Rieder has recently published, in the *Fortschritte a. d. Gebiete der Röntgenstrahlen*, viii, No. 3, a fine collection of radiograms of the stomach and intestines. Schüle's findings confirm them and Rieder's conclusions in every particular. Radiograms in case of not too corpulent persons throw light not only on the topography but also on the motor functions of the stomach to a surprising degree. In conclusion Schüle warns that the repeated giving of bismuth should not be regarded as so innocent a matter as is generally assumed. To date no injury has been reported from its internal administration, but instances are on record of harm from its external use. In his tests he found that the findings of percussion, the patient standing, after a test meal, always coincided with the Röntgen findings.

32. **The Mucus in the Stomach.**—Schütz has been studying the pathologic variations in the secretion of mucus in the stomach. His observations were made one hour after a test breakfast, examining the stomach content obtained by expression. He also examined the rinsing water obtained after the stomach has been emptied and rinsed clean, and the stomach contents obtained by rinsing and expression of the fasting stomach. He tabulates the findings in 110 patients with various stomach affections on whom these three tests were made. In 52 per cent. of the cases the mucus was found in excessive amounts, while in the rest it was scanty or lacking altogether. The latter group included 9 cases of achylia, 8 of motor insufficiency, 7 of gastralgia, 9 of gastric neurosis, 4 of anacidity, 3 of hyperacidity, 1 of ectasia, 2 of chronic catarrh and 1 each of ulcer, subacidity, cicatricial stenosis of the pylorus, gastro-duodenal, obstruction, nephrolithiasis, acute dyspepsia and icterus. In 28 cases of chronic gastric catarrh the mucus was found excessive at all three tests, as also in 6 cases of cancer of the stomach, in 1 of cancer of the liver and in 1 of ulcer.

The mucus was found excessive in the second and third tests alone in 10 patients, including 1 case of ectasia, 2 of motor insufficiency, 1 of gastroenterorrhea, 1 of chronic nephritis with dyspepsia, and in 3 of gastric neurosis. The mucus was found excessive only in the second test in 2 cases of motor insufficiency and in 1 of a gastric neurosis, and only in the third test in 7 cases, including 2 of subacidity and 1 each of subacidity, enteroptosis, hyperacidity, ulcer, neurosis and cicatricial stenosis. He reviews in detail the groups of these various affections, and believes that his research will establish the conception of catarrh of the stomach on a more solid foundation, although he does not attempt to draw any general conclusions at present.

33. **Sensibility of Abdomen.**—Kelling summarizes the conclusions of his extensive study of the subject as follows: It is necessary to investigate much more closely than has yet been done the conditions of sensibility in the region of the cecum. The sensibility of the skin must be distinguished from the tender points in the musculature and the latter from the tender points in the sacral hollow of the pelvis, and each and all should be compared with the symmetrical points on the other side of the abdomen. The tenderness at McBurney's point is purely nervous. At this point the nerves of the appendix correspond with those of the abdominal wall above, so that the condition of irritation in the sympathetic plexus of the region of the cecum induces hyperesthesia in the intercostal nerves and also at the places where the cutaneous nerves pass through the fascia. There is another tender spot in the sacral hollow of the pelvis, the ileocolic plexus, which may be hypersensitive and tender in case of essential irritative conditions, such as hysteria, neurasthenia, etc., or by radiation, as in case of appendicitis, colitis, cholelithiasis, etc. Hence tenderness in this region can not alone serve to diagnose appendicitis. Palpable anatomic findings are the only reliable basis for the diagnosis. For the differential diagnosis between appendicitis and cholecystitis, even icterus is not decisive except when it occurs without fever. Bacteria may be carried from the appendix into the liver and thence into the bile, and may thus induce cholangitis and cholecystitis. This is why icterus is not a rare accompaniment of appendicitis. It also explains the frequent combination of appendicitis and of subsequent cholelithiasis. When there is a striking lack of tenderness in the pathologic resistance and its vicinity, it is safe to assume that the sensation of pain, if it exists, is falsely located, and that it should be referred to the more centripetal sympathetic plexus or to the skin, and in the latter event to the symmetrical point opposite. In attacks suggesting appendicitis and requiring operation, special attention should be paid to the gall-bladder, particularly when the findings in the appendix are comparatively trifling. On the other hand, the appendix should always be investigated during an operation for gallstones. In cases suggesting appendicitis or a gallstone affection, without decided palpable findings, the diagnosis should be left in suspense, but the treatment should be that of the more serious affection, namely, of appendicitis. The article is illustrated and the various points of special sensitiveness in the abdomen are described and the anatomic conditions explained.

34. **Early Diagnosis of Rectal Cancer.**—Boas addresses this article to the general practitioner, expatiating on the latter's responsibility for the disaster sure to follow the overlooking of malignant disease in the rectum until the time for operation has passed. In 80 per cent. of his 83 cases of carcinoma of the rectum the growth was inoperable when first seen. In several cases some physician had made a supposed careful examination of the rectum and yet had failed to discover it. In other cases the physician had detected the growth, but had not insisted on immediate operation, and the patients had wavered long before consenting to an operation, possibly wasting time with quacks in the interim. Boas does not have much hope of effectually influencing the public by newspaper articles, lectures, etc., along the lines of Winter's anticancer campaign (mentioned in the news columns of the last volume). When people are well they pay slight attention to warnings or admonitions and soon forget them. He suggests as a more effectual measure that physicians should have printed on the backs of their prescrip-

tions a series of warnings in regard to the first signs of cancer, and what should be done, similar to Winter's warning in regard to cancer of the uterus. Patients getting the prescriptions would read the warnings on the back. When people need prescriptions their minds are turned to thoughts regarding disease, consequently the warnings would make more impression than at other times and places. He says that if a hundred physicians would take this step, others would soon follow, and the constant reiteration of the warnings at an impressionable period could not fail to impress the public in time. Cancer of the rectum occurs, according to his experience, in about a third as many cases as cancer of the stomach (245), and nearly as often as cancer of the esophagus (100). As the food has been digested and assimilated in the upper part of the digestive tract, persons with cancer of the rectum do not grow thin and weak but may present a blooming aspect and gain in weight. Habitual constipation was noted in the history of 15 and hemorrhoids in 22 of his patients. The classic triad of symptoms, tenesmus, obstruction or diarrhea and blood and mucus in the stools, are not observed at first in every case. In some of his patients the first symptoms were violent colic pains recurring at intervals in the abdomen or stomach, and in other cases pains in the region of the sacrum or coccyx. Such cases suggest the necessity for examination of the rectum, even when the symptoms point to other organs. In certain cases bleeding from the rectum was the first symptom to attract attention. The bleeding simulated hemorrhoidal hemorrhages, especially as it so frequently affects persons already subject to hemorrhoids. The same applies to tenesmus, which is supposed to be frequent in case of hemorrhoids. His experience has been rather against this assumption. Tenesmus with hemorrhoids is more intermittent than that accompanying cancer of the rectum. In every case of tenesmus it is the physician's first duty to determine its cause. In at least 25 out of his total of 83 cases the tenesmus was not observed until from one to twenty-four months after the appearance of other symptoms, thus being a tardy symptom in two-thirds of the cases. The course of rectal cancer may be long or short. In 24 cases in which the first symptoms had been noted only from three to twelve weeks before, he found 6 in which the growth was already inoperable, and only 2 of the patients survived the operation for any length of time. On the other hand, he encountered cases in which the symptoms dated from months and even two or three years before, and yet the growth could be successfully removed. Five of his 83 cases of rectal cancer were in diabetics, which he regards as more than a mere coincidence. In diagnosing this condition he calls attention to the odor of the underclothing in cases of rectal cancer, and it may be possible to detect spots on the underclothing with the same fetid, not fecal, odor. Another important sign is the stools. The patients complain of several watery discharges during the day, sometimes containing hard lumps of feces. In case of ordinary enteritis or nervous diarrhea, the amount passed is comparatively large, but with rectal cancer the amounts are remarkably small, mere spurts. Boas never fails to inquire as to the character of the passages in every case of diarrhea that he encounters. Another diagnostic point is that the diarrhea in these cases persists unmodified by dietetic or vigorous medicinal measures. When he learns this fact in regard to a patient, he never wastes a moment before examining the rectum for cancer. Still another sign of this "false diarrhea" is that the intestines are not empty, but contain lumps of feces, especially in the descending colon and the sigmoid flexure. This confirms the diagnosis of primary obstipation. Simple chronic diarrhea empties the intestines, but does not cause an increase in the indican in the urine. In the false diarrhea from obstruction, indican is found abundantly. Examination of the urine may therefore prove suggestive. Even if nothing suspicious can be found in the rectum after digital and ocular examination, the search should not be abandoned until after the sigmoid flexure has been investigated also. The prognosis may vary with the variety of the cancer, and hence microscopic examination is advisable. If the growth is inoperable, palliative treatment gives more gratifying results in these cases than with cancer elsewhere. The physician should aim to keep the general health good, to keep the passage open and to avoid everything that might irritate the carcinoma.

Ordinary diet, including beans, peas, etc., is appropriate; only irritating hulls, skins, etc., must be avoided, the articles of food being prepared universally in the form of purées. Sugar, acids, salts, fats and oils should predominate as in any anti-constipation diet. Mild laxatives are also required. The tenesmus must be kept under control by these measures, with opiates as the last resort. He refers to one patient kept in comparative health for four years by these means.

36. Treatment of Psoriasis.—Düring thinks that not enough attention is paid to hydrotherapy in the treatment of psoriasis, especially sweat baths with dry heat. Douches, alternating hot water for two minutes and then cold water for two seconds, are another useful measure. The sensitiveness of the skin must be carefully determined for each individual case to gauge treatment. As a rule, he prefers oil of cade to chrysarolin and pyrogallol. The patients should be moderate in the use of alcohol, coffee and tobacco, and should avoid a "too nourishing" diet in general as tending to favor eruptions. Internal treatment of psoriasis he considers uncertain, useless and even harmful in some instances. Arsenic sometimes aggravates the symptoms or induces others. The salicylates and iodine internally have proved ineffectual in his experience, although he acquired the impression in some cases that potassium iodid internally promoted the action of external medication. He warns against thyroid treatment. In regard to prognosis he is quite pessimistic. The treatment which may cure one patient may have no effect on another; in a third, the old eruption may subside, but another follow close, and in a fourth it may transform a torpid process without subjective symptoms into an annoying and generalized affection, disturbing the general health.

43. Ortho-percussion.—Curschmann has found Goldschelders' technique of ortho-percussion extremely reliable, the results coinciding invariably with the findings of ortho-radiography. He has the patient recline and percusses during shallow respiration. The results have proved so reliable that he recommends this method of percussion as a valuable aid in diagnosis. In combination with the determination of the absolute dullness it allows a more complete oversight of the heart and main arteries than has hitherto been attainable in any way.

46. Dangers from Cheap Metal Spoons.—Steinheil gives an illustration of five spoons which he found used daily in cooking. The cheap alloy of which the spoons was made easily crumbled or melted off, so that fragments of the spoons dropped into the food and were probably eaten with it.

48. **Cardiac Neuroses.**—In this clinical lecture Rumpf describes the various neuroses affecting the heart and the means of relieving them. In all forms the entire mode of life must be regulated; eating, drinking, sleep, exercise and gymnastics as well as mental activity must all be supervised. Injurious influences in the daily life must be eliminated after careful study of the anamnesis. He thinks a moderate altitude is better for heart neuroses than the seashore. In attacks of tachycardia, deep breathing while reclining may be found useful, both in curing and in preventing an attack. Ice to the heart has also done good service in some cases of heart neurosis on a hysterical or neurasthenic basis. One group of heart neuroses which prove especially obstinate to treatment are those that follow over-exertion or trauma, especially excess in sports. The most essential symptom in this class is the great acceleration of the heart action at the slightest exertion, perhaps at the slightest movement. There is also weakness, with pallor and sometimes loss of weight. These cases require rest in bed for weeks or months, with care as to nourishment, avoidance of alcohol, coffee, tea and tobacco. Carbonated saline baths and cautious respiratory exercises while reclining, vibration massage and electricity may be tried. The psychic treatment is of great importance. The trouble may last for months, if not for years, and frequently entails arteriosclerosis. There may have been dilatation of the heart, but it has subsided by the time the physician sees the patient, and foci of degeneration may have been left which escape diagnosis. Sometimes a heart neurosis of this kind follows an injury of the skull. In several cases of this kind he has observed consecutive arteriosclerosis develop in a few years in young persons who never had used tobacco or alcohol to excess. So long as no organic affection can be detected in these traumatic cases they must be classed as neuroses. Cardiac neuroses may be induced from the digestive tract by direct mechanical influences, and further by reflex phenomena from the most varied points in the abdomen. The false angina pectoris and tachycardia that may result should be treated by emptying the stomach and intestines. Lavage of the stomach will relieve or possibly a glass of warm water in the morning before eating, followed by shaking the stomach through the abdominal wall. Drinking tepid water and putting the finger in the throat will induce a desire to vomit, which empties the stomach as the pylorus opens at the same time. The diet should be regulated. Coffee, especially after meals, is liable to interfere with digestion, prolonging the stay of the food in the stomach and favoring abnormal putrefaction. Tea may be allowed, but not in sufficient amounts to distend the stomach. Another form of neurosis is observed in obese patients whose weight has been rapidly reduced, allowing undue movability of the heart.

57. **Treatment of Inoperable Cancer of the Uterus.**—Chrobak remarks that in inoperable cases of cancer of the uterus the condition can be relieved by a partial operation to a greater extent than is generally recognized. He has had a patient gain 77 pounds after a palliative operation on an ovarian cancer. He does not believe in telling the patient that she has malignant disease, preferring to persuade her to submit to an operation, possibly adding that treatment by other measures is not so sure of results and that if intervention be postponed it may come too late. He regards it as a greater satisfaction than the most brilliant operation when he has succeeded in winning the confidence of a cancer patient and has been able to keep her during the entire course of the disease unaware of its true nature and full of hope until death brought release. The physician should strive to ward off injurious influences and should vary the therapeutic measures, keeping hope alive. Curetting and cauterizing the growth will frequently hold it long in check. His experience has confirmed Lomer's to the effect that the results are more favorable when there is fever afterward. There is certainly, he is convinced, a difference in the course of an open and a covered cancer. When he has covered the growth after an operation with a shield of mucosa, local recurrence was tardier than when it was left uncovered. Even when a palliative operation merely promotes cleanliness and rests the patient it is surely worth while. Martin had a patient live 54 months after curetting an inoperable cancer, Gebauer one who lived over five years, and Eyring had one who lived over three years. Chrobak performed 408 such palliative operations in his clinic between 1890 and 1900. In 1903, 7 of the women were still living, 2 after an interval of two or three years, 4 after three or four years and in 1 case of epithelioma of the cervix the patient lived eleven years after the palliative operation. Nine of the patients lived for three years, 4 for three or four, 2 for five or six, 1 for ten

and 1 for eleven years. In his private practice he had a patient survive for five years who required curetting of recurrences several times and was then lost to sight. In another case he curetted, in 1884, a carcinoma of the vaginal portion of the cervix encroaching on the vagina, in a woman of 32. The growth proved to be a soft, unusually vascular canceroid. Hemorrhage recurred a few months later, indicating a new scraping, and a recurring growth was curetted away in 1884. Since that date the growth has healed over completely, the patient is still in perfect health and has married a second time, although sterile in this latter marriage. In another case a carcinoma of the body of the uterus was curetted in 1888; there has been no recurrence to date. He has repeatedly kept patients in good health for six years by curetting at the first recurrence of symptoms, sometimes repeating the procedure eight or ten times on the same patient. These results are possible only in private practice. In the public hospitals the patients seldom return often enough, and if they learn the true nature of their trouble they are liable to resort to swindlers and quacks. He lays great stress on refraining from calling the scraping an "operation." The patient should be told that it is merely a harmless intervention which the family physician or the surgeon will possibly or probably have to repeat several times. The term "operation" frightens the patient too much, and she shrinks from a repetition of an operation. The family should always be fully informed in regard to the circumstances. In curetting he uses a large sharp spoon under general anesthesia, after careful disinfection, proceeding as rapidly as possible on account of the bleeding, which generally ceases when sound tissue is reached. He then takes a small sharp spoon and scrapes out the rest of the cancer in its remotest nooks, supporting the growth with the finger introduced in the rectum. When everything accessible has been scraped away he rinses and sponges the tissues dry and then cauterizes. He has used the actual cautery, but thinks that it does not penetrate into the crevices as well as a fluid caustic. The cancers which remained free from recurrence the longest were all cauterized with crude fuming nitric acid. He applies it on a stick or roll of asbestos, the asbestos fibers forming a brush, or with a cotton-wool stick. He never sprays the fluid, as it is liable to burn the sound skin or the physician's hands. Even the fumes are caustic and must be blown away. The scab is thrown off in two or three weeks, and granulating surface is left, whose healing can be promoted with iodine or silver nitrate solutions. Suspicious points can be treated again with the nitric acid or otherwise. There is always danger during curetting of perforating into the bladder, rectum or peritoneal cavity, and the operation should not be undertaken until visual inspection of the bladder or rectum has shown that there is no extensive cancerous infiltration of the dividing wall. Perforation into the peritoneal cavity is not so dangerous as is generally supposed if it is recognized at once and further intervention suspended. After the cauterization, dry powder scattered in the vagina or applied on gauze will help to dry up the discharge better than attempting to keep the vagina clean by injections of astringents or disinfectants. They tend to keep up the discharge. In his experience the best powder for such local use is a combination of iodoform with tannin or charcoal. In conclusion he urges that in such a case the physician should conquer his personal diffidence and strive to keep the patient in his charge. In changing her physician she is liable to learn the true nature of her trouble, which may nullify all the previous efforts to save the doomed woman from despair.

60. Bullet Wound of Skull and Epilepsy.—A young man witnessed the burning of his parents and in his grief seized a revolver and shot himself in the head. Splinters of bone were removed on several occasions afterward, as symptoms of transient paralysis and epilepsy developed, but two years after the accident a box fell from a height on the defect in the skull and severe chronic cortical epilepsy developed at once. The two places where there were gaps in the skull were closed with celluloid plates and the epilepsy vanished. The cure has been permanent for eight years to date.

63. Epidemic Cerebrospinal Meningitis.—Weichselbaum states that during an epidemic there is always a possibility

that a few cases may be encountered which do not belong to the epidemic class. It seems to be an established fact, however, that the great or protracted epidemics of cerebrospinal meningitis are always due to the *Diplococcus intracellularis*.

65. Cholera Vibrios Without Cholera.—The report of examination of cadavers of Mecca pilgrims has already been mentioned in these columns. In 6 out of 38 in which dysentery had been the cause of death, Prochnik found cholera vibrios without any evidences of cholera, past or present. Although harboring virulent cholera bacilli, the individuals had not become infected nor infected others, as not a case of cholera was known throughout the Mecca region during the season. The article is an interesting account by a medical man of the great Mecca pilgrimages. Prochnik is consul for the region and has charge of the sanitary regulations, with offices at Djeddah.

66. Fixation of Liver on Account of Cirrhosis.—Nikolic describes a case of alcoholic cirrhosis of the liver in which hepatoxy was done by Czerny. The patient succumbed almost immediately to hemorrhage from the stomach. The pressure of the heavy overhanging liver on the stomach had interfered with its circulation and compressed the pylorus. A patch of necrosis resulted with erosion of the gastroduodenal artery, a protruding portion of the cirrhotic liver lay over the patch of necrosis and acted like a plug for the eroded vessel. When the heavy liver was raised up and fastened to the abdominal wall this removed the stopper over the injured vessel and also removed the obstacle to the circulation. The result was the fatal hematemesis. In another case the postoperative diagnosis was round ulcer of the stomach, with incipient cirrhosis of the liver. Treatment was by posterior gastroenterostomy and hepatoxy, and the patient made a smooth recovery and was soon dismissed.

71. Lymph Gland as Protecting Organ Against Tuberculosis.—Bartel has been conducting researches to learn more about the incipient stages of tuberculosis infection and has arrived at various conclusions on the way. Among them is one to the effect that he can not be mistaken in assuming that the lymphocyte plays the principal part in the fight with the tubercle bacillus. The normal lymphocytes of an animal comparatively resistant to tuberculosis (sheep) are able to make virulent tubercle bacilli avirulent, which can then be injected into guinea-pigs without resulting infection. Long contact is required in the test tubes before the virulence is thus abolished, but this corresponds to the long period of incubation or latency of tuberculosis infection in general. The avirulent tubercle bacilli after contact with the lymphocytes lose their destructive and chemotactic properties, also the power of proliferating, and he believes that they will prove an effective vaccine material, inducing active immunity. He is convinced also that the lymphocyte-producing organs of animals thus actively immunized will elaborate a substance which will have an attenuating and inhibiting action on tuberculous affections in other animals. Further researches in this line are now under way.

72. Experimental Syphilis.—Kraus has been experimenting with syphilis in monkeys, treating it according to the technique of the Pasteur treatment of hydrophobia. His experiences have been limited, but the impressions derived were decidedly favorable.

81. Diabetes Insipidus.—Schmidt has been impressed with the constancy of constipation in the previous history of certain patients with diabetes insipidus and the remarkable subsidence of the polyuria when podophyllin was given. Defective skin functioning was another constant feature of the clinical picture. The artificial hyperemia induced by the drug in the intestines diverts the blood from the congested kidneys and gives the atonic kidney vessels a chance to recover their tone. Sweat baths may have the same kind of revulsive effect. Treatment of the cases of polyuria accompanied by diminished cutaneous function and constipation, should be directed to reducing the congestion in the kidneys resulting from loss of tone by the capillaries of the organ. Reduction of the intake of fluids will help, as also laxatives and diaphoretics. He prescribes 1 gm. (about 15 grains) of podophyllin in 40 pills,

ordering one or two pills a day, with physical measures to promote action of the skin, warm clothing, a southern climate, etc. He describes 3 cases in detail and reviews the literature.

82. **Secondary Parotitis.**—Pichler's 4 cases include 3 secondary to pneumonia and 1 following typhoid.

83. **Recurring Diphtheria.**—Zucker states that out of 2,323 diphtheria patients treated with serum, 21 returned after an interval of from one month to over five years with a second attack and 3 with a third. The course of the recurring disease was not essentially different from that of the first attack, and no difference could be observed in the effect of the serum treatment.

88. **Etiologic Treatment of Syphilis.**—Spitzer has applied on 15 syphilitic patients the technic advocated by Kraus above, treating them with a suspension of tissue from syphilitic scleroses, diluted to .5 and 5 per cent. The technic was the same as for Pasteur injections in hydrophobia. Between eleven and twenty injections were made; 7 of the patients were apparently uninfluenced by them. Three others have presented no further manifestations of the syphilis during the ten and twelve months they have been under observation, and in the remainder the manifestations were very tardy in developing and were very slight. The injections were made from two to four weeks after infection. No inconveniences of any kind were observed from them, and the inguinal buboes in all subsided with striking promptness.

91. **Death from Electric Accidents.**—Jellinek concludes his monograph with the assertion that death from electric accidents in the majority of cases is merely apparent death. The menacing symptoms are frequently of a transient nature, tending to improvement, the vital functions in many cases being merely transiently disturbed or inhibited, and recovering if efforts at resuscitation are kept up long enough. The electricity has a double action. If the material changes are not too pronounced, the psychic phenomena may right themselves in time.

100. **Passive Hyperemia in Gynecology.**—Bauer gives an illustration of the speculum tube he uses for inducing passive hyperemia in the vagina. In one case of amenorrhea of two years' duration he succeeded in re-establishing menstruation by five applications of the speculum for five minutes at a time in the course of five days. A number of other patients were not benefited. The best results were obtained in chronic metritis. In one case an attempt to use the speculum before inducing abortion brought on an unusually severe hemorrhage.

101. **Veronal Poisoning.**—Göringer states that since Kress published in the *Neue Therapie* for September, 1905, a list of cases of acute and chronic veronal intoxication he has had occasion to observe the following case: A woman of 30, who had twice been under treatment for neurasthenia, consulted her physician on account of a felon and, asked for a hypnotic to enable her to sleep. He prescribed 1 gm. (about 152 grains) of veronal (diethylmalonyurea) in 20 powders, with instructions to take one powder on retiring. As she felt no effect from one powder, she took eight more, thus ingesting 4.5 gm. (about 68 grains) of the drug, and slept till morning. She awoke with nausea, vomiting, headache, somnolence and staggering gait, subnormal temperature, contracted pupils and sluggish pupil reaction. Twelve hours after taking the drug her stomach was washed out with a solution of 5 gm. of tannin in 5 liters of water (about 15 grains to the quart), the intestines were flushed high with water, and caffeine was injected and black coffee given as for morphia poisoning. Vomiting continued during the day, with some somnolence, but the patient rapidly recovered and was dismissed cured the fourth day. As at least twelve hours had elapsed before treatment was commenced, the veronal must have been very slowly absorbed. It is not very soluble in water. [In Hoppe's case of chronic veronal poisoning, reported in society proceedings in the *Deuts. med. Wochsft.* for June 15, and in the *Therap. Monatsh.* for August, 1905, a man, aged 23 years, under treatment for inebriety, was given occasionally 0.5 gm. (7.5 grains) of veronal to relieve insomnia. About seven weeks later the patient began to

sleep so soundly until midday that it was difficult to awaken him. He resorted to the use of 8 to 10 cups of strong coffee and tobacco smoking to keep active during the afternoon, and exhibited characteristics of drunkenness. It was ascertained that he had been taking daily from 2 to 3 gm. (31 to 46 grains) of veronal. In the discussion of this case Dr. Hoeffmann referred to 2 cases or the same form of chronic poisoning. One patient was a neurotic and showed marked psychic disturbance after comparatively moderate doses of the drug; among other symptoms, the speech was like that of a drunken man. The second patient, a former morphine-eater, used daily from 2 to 3 gm. (31 to 46 grains) of the veronal and showed marked excitement, with suicidal tendency, and the same peculiar speech. The diagnosis in this case was made principally from the appearance of drunkenness, especially in regard to the speech. Hoeffmann remarked that the condition was worse than that of the previous morphine addiction in so far as there were no free intervals.—Ed.]

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

MATERIA MEDICA, PHARMACY AND THERAPEUTICS, Including the Physiological Action of Drugs, the Special Therapeutics of Disease, Official and Practical Pharmacy, Abbreviations, Directions for Prescription Writing and Avoiding Incompatibility, also the Antidotal and Antagonistic Treatment of Poisoning. By S. O. L. Potter, A.M., M.D., M.R.C.P. Tenth Edition, Revised and in greater part Rewritten. Cloth, Pp. 914. Price, \$5.00 net. Philadelphia: P. Blakiston's Son & Co., 1906.

AN ATLAS OF HUMAN ANATOMY. For Students and Physicians. By C. Todd, M.D., assisted by A. D. Rosa, M.D. Translated from the Third German Edition and adapted to English and American and International Terminology by M. E. Paul, M.D., M.R.C.S., L.R.C.P. Sixth Section, 6. Neurology; II, the Organs of the Senses. Cloth, Pp. 955. Price, \$4.75. New York: Reban Company, 1904.

SQUIBB'S MATERIA MEDICA. A Complete Alphabetical List of all the Squibb products, embracing the articles in the U. S. Pharmacopoeia (8th revision), and the National Formulary, together with general and Chemical, Pharmacological and New Remedies in general use. 1906 edition. Part II. Cloth, Pp. 394. New York: E. R. Squibb & Sons.

THE PRACTICE OF MEDICINE. A Text-book for Practitioners and Students, with Special Reference to Diagnosis and Treatment. By J. Tyson, M.D. Fourth Edition, Revised and Enlarged. 240 Illustrations, including colored plates. Cloth, Pp. 1305. Price, \$5.50 net. Philadelphia: P. Blakiston's Son & Co., 1906.

BIRDS FROM MINDORO AND SMALL ADJACENT ISLANDS. II. NOTES ON THREE RARE LEZON BIRDS. By R. C. McGregor. Publication of Department of the Interior Bureau of Government Laboratories. No. 34. October, 1905. Paper, Pp. 31. Manila: Bureau of Public Printing, 1905.

TRANSACTIONS OF THE MISSISSIPPI STATE MEDICAL ASSOCIATION, Thirty-eighth Annual Session held at Jackson, April 19-21, 1905, with Report on Medical Topics, Roll of Members, Constitution and By-laws. Cloth, Pp. 230. Mississippi: Journal of the Mississippi State Medical Association.

SURGICAL TREATMENT OF CHRONIC SUPPURATION OF THE MIDDLE EAR AND MASTOID. By S. Oppenheimer, M.D. Illustrated by 46 half-tone Plates, containing 64 figures and 27 key plates, etc. Cloth, Pp. 425. Price, \$6.00. Philadelphia: P. Blakiston's Son & Co., 1906.

RELATIONS OF PUBLIC SCHOOL TEACHERS TO CORRECTIVE GYMNASIUMS. By G. R. Albee, Director of Physical Training State Normal School, Cedar Falls, Iowa. Paper, Pp. 16. Price, 10c. Boston: Published by the American Gymnasia Co.

PROCEEDINGS OF THE CONNECTICUT MEDICAL SOCIETY, 1905. One Hundred and Thirtieth Annual Convention held at Hartford, May 24-25. Published by the Society. Cloth, Pp. 588. Bridgeport, Conn.: Press of the Farmer Pub. Co., 1905.

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF THE STATE OF ALABAMA. (The State Board of Health) Organized, 1847—Meeting of 1905: Montgomery, April 19-22. Cloth, Pp. 587. Montgomery, Ala.: Brown Printing Co., 1905.

TWENTY-THIRD ANNUAL REPORT OF THE STATE BOARD OF Health of Indiana, for the Fiscal Year ending Oct. 31, 1904, and Statistical Year Ending Dec. 31, 1904. Cloth, Pp. 282. Indianapolis: W. R. Burford, 1905.

PATENT FOODS AND PATENT MEDICINES: Two Lectures by R. Hutchison, M.D., F.R.C.P. Second edition. Paper, Pp. 47. Price, 18 net. London: J. Bale, Sons and Danielsson, Ltd., 1906.

AN INVESTIGATOR'S MANUAL for the Settlement of Accident and Health Claims. By C. H. Harbaugh, M.D. Flexible Leather, Pp. 304. Price, \$2.00. New York: The Spectator Company.

A MANUAL OF PHARMACY for Medical Students. By M. F. De Lorme, M.D., Ph.D. Cloth, Pp. 206. Price, \$1.00 net. New York: The John C. Lindsay Co., 1905.

THE PHYSIOLOGIC AND LEGAL STATUS OF THE FETUS IN UTERO.*

W. H. SANDERS, M.D.
Health Officer of Alabama.
MONTGOMERY, ALA.

The two most important events connected with a life-history are its beginning and ending.

Embryology has persistently sought to discover and to interpret the earliest manifestations of the former, while pathology, with equal tenacity of purpose, has endeavored to ascertain the causes and incidents of the latter. So far as the beginning of a life-cycle is concerned, embryology has thoroughly established the doctrines of gamogenesis and agamogenesis, the former being the rule among the higher orders of plants and animals, the latter among the lower orders. Reproduction among human beings must, therefore, obey the law of gamogenesis; hence, two ancestors—male and female—contribute to the origin of every new member of the human race, the contributing elements being spermatozoon and ovum, respectively.

While these germ-cells possess inherent vitality and motor power, especially the spermatozoon, neither one can separately and alone evolve itself into a higher or more complex morphologic entity. Put the two together, however, under favorable conditions, and a new unit results, one capable, under proper environments, of evolving itself into a fully-developed human being, that is, the new unit represents all of the potentialities of which the future adult becomes the outward and visible expression.

In contributing the germs they respectively furnish, the male and female have done all they can do toward the creation of the new unit and toward its endowment with physiologic and psychologic functions similar to their own. From that time forth the new being, possessing all of the attributes of living bioplasm—motion, absorption, sensation, and fission, or multiplication—must be the architect and builder of its own body. True, for nine months the female performs the essential and hospitable function of hostess, and generously supplies the young, and presumably welcome, guest with oxygen, inhaled through her own lungs; with food, elaborated in her own digestive system, and with warmth supplied by her own blood, but in fulfilling these high functions she is simply furnishing the material, the brick and mortar, so to speak, out of which the young builder must erect its own corporeal superstructure.

In the work going on, the part played by the female corresponds with the office of brick and mortar carrier,

that by the young builder, with the office of skilled artisan, who takes hold of the materials brought and puts them together in the shape and form of a human body. The new being as it grows and develops is not the passive result of work done by the physiologic forces of the female, but is an autochthon, using, however, very refined material furnished by the hostess. The principle is precisely the same as one that prevails in social life. A hostess places dishes, delicious and wholesome, before her guests, but is powerless to force them to partake thereof; they must, by their own volition, take hold of and appropriate the food brought within their reach.

Science does not forbid, on the contrary justifies, the belief that, could the fertilized ovum, before it has formed attachments to the womb in which it receives its fertilization, be transferred without violence to another womb in a similar condition to the first, its career of growth and development might proceed undisturbed. Indeed, could the transfer be made to an artificial womb, or incubator, in which the conditions were identical with those of the natural womb, its growth and development might still proceed undisturbed. The conjunction of spermatozoon and ovum must, therefore, be a great biologic event, one that endows the newly-formed unit with physiologic functions and psychologic attributes; indeed, makes it, in a qualified sense, an independent human being. Although the powers of this new being are feeble, its potentialities are great, the evolution of which constitutes the growth, development, and achievements of its life-history.

The cardinal postulate I desire to emphasize is that the vitality, the life-force, and the physiologic functions of the new being reside within itself and not in the hostess. As has been said, the latter sends blood to the fetus, freighted with food and air, but she is powerless to force it to accept either; the new being eats because it is hungry and breathes because it feels the need of oxygen, both acts being vital efforts of its own. Soon after receiving its endowment of physiologic functions the new comer settles down in its velvety and temporary home, prepared by the proliferating lining of the maternal womb, and dominated by an instinct, yea, an intelligence, coeval with its own corporeal origin, proceeds to differentiate itself into bone, sinew, tendon, muscle, blood vessels, viscera, brain, and nerve, and with the skill of a consummate artist fashions these in miniature of an adult human being, the highest type of animal life. The fetus performs these physiologic functions by virtue of its own vitality and power, originally derived, it is true, from the two parental germs, but when these have been consolidated into a new unit—a tertium quid—a self-acting and, in a qualified sense, a self-sustaining human being has been created.

At the end of nine months the silent and unseen artist has filled his temporary home with his living self, whereon the hostess by means of forces marvelously

*Read in the Section on Obstetrics and Diseases of Women of the American Medical Association at the Fifty-sixth Annual Session, July, 1905.

scientific and practical ushers him into the outside world as a plump and rosy baby. When was that baby born, a few minutes ago or nine months ago? Science and logic give one and the same answer. If birth means the act of coming into life, as the dictionaries tell us, unquestionably the baby under discussion came into life nine months ago, and at the end of that period simply changed its domicile. Why not, then, abolish the term conception, which is liable to be more or less misleading and confusing, especially to the lay mind, and substitute for it the more scientific and correct term, birth? This done, then, the one term, delivery, either premature or at full term, would adequately express the transition of the child from intrauterine to extrauterine life. Besides, the adoption of this nomenclature would help to clarify the entire subject of fetal life and would lead to the enunciation of definite, inflexible, and absolutely correct principles of jurisdiction applying thereto. If the baby in question is a living human being when delivered, was it not a living human being the day before, the month before, six months before, eight months and twenty-seven days before? Can a point of time betwixt conjunction of the parental cells and the delivery of the child be fixed before which it did not possess the nature of a human being and after which it did possess the nature of a human being? Did its nature undergo any change between the time at which conjunction of the male and female germs occurred and that at which the baby appeared in the outside world? Was not the nature of the baby the same from the beginning to the ending of its uterine life? Was it not from first to last simply a question of the growth and development of one and the same being, and after the completion of the period of uterine life will it not continue to be a question of the growth and development of one and the same being up to physical maturity?

With these questions answered in the affirmative, as they must be, we are forced to concede that when in the red-hot furnace of congeniality two germs—male and female—are brought together that fuse themselves into one, a new being, crowned with humanity and mentality, comes into life. If this be true, does not the new being, from the first day of its uterine life, acquire a legal and moral status that entitles it to the same protection as that guaranteed to human beings in extrauterine life? Indeed, should it not receive greater protection, for the reason that to the nature of a human being it adds the condition of utter helplessness, a condition that should appeal in mute, but sublime eloquence to the manhood, the womanhood, and, above all, to the motherhood, of those who can shield and protect it? Lives there a man or woman who would assault and slay a little, laughing, prattling babe? If that be a crime from which the coldest-blooded villain would recoil, how much more a crime to assault and slay an innocent babe quietly sleeping in what should be an impregnable fortress—a babe whose voice is hushed and can not be raised in piteous cry for mercy or for help!

Objection to the use of the terms, birth and delivery, in the senses suggested, might be raised on several grounds: First, that it would involve the date of every birth in more or less uncertainty; secondly, that the fact of a birth could not be certainly known for four or five months after it had occurred; thirdly, that no practical benefit would result from the adoption of the proposed nomenclature. Admit that these objections are entitled to more or less weight, yet, when compared with the ad-

vantages that would accrue from the change of nomenclature proposed, the objections dwindle into insignificance. A simple formulation of the advantages will be sufficient to force conviction of the utility of the proposed nomenclature:

1. It would be essentially and scientifically correct to locate birth where and when it actually occurs, in spite of the fact that several months would usually elapse before it could be known that a birth had certainly taken place.

2. It would place a pregnancy, from the first day of its probable occurrence to its termination, on the high legal and moral grounds it deserves to occupy.

3. It would dignify the position of the *fetus in utero*, and would establish beyond all doubt or confusion the right of the fetus to the same protection, moral and legal, as is accorded to human beings who have completed the period of their uterine existences.

4. It would unify the terms, fluxion, abortion, and miscarriage, under the one term, premature delivery; then, two expressions, premature delivery and delivery at full term, would cover the entire subject.

5. It would enable lawmakers to enact clear and definite laws for the protection of the *fetus in utero*, which laws, jurists and juries could administer without doubt or confusion.

6. It would have a strong tendency to promote virtue and to prevent crime, and to build up in every community a positive demand for the protection of human life at its tenderest and most helpless period; it would tend to educate the people on a subject in reference to which they stand in great need of education and would thereby save the lives of many innocent and undelivered babes.

If the argument thus far be sound and tenable, does not the legal status of the fetus become clear and fixed? It is not strange that before science had ascertained the steps and stages of reproduction the law providing for the protection of the fetus should have been inadequate, but after these steps and stages became definitely established no inadequacy on this point should have prevailed. The common law is conspicuously defective in its provisions for the protection of the fetus. The following quotations on this point are made from the American and English Encyclopedia of law: "According to some authorities, it never was an act punishable at common law to commit abortion with the consent of the mother, provided it was done before the child became quick; but others are not disposed thus to restrict the criminal act, and hold that it may be committed at any stage of pregnancy. If the abortion was committed after quickening, it was punishable only as a misdemeanor. If done without the woman's consent, the act was held to constitute an aggravated assault."

Inasmuch as the common law was wholly inadequate for the protection of the fetus it became imperative that this defect should be supplied by statute law. Quoting from the same authority cited above, it is gratifying to find the following statement: "The statutes enacted on this subject in most of the states fail to draw any distinction between the commission of the offense, or attempt at commission, before and after the quickening of the child in the womb, making it a felony in either case. But some states still retain the distinction, punishing the act or attempt more severely when done after quickening. In Michigan it is essential that the child be quickened. The means denounced by the various statutes are the unlawful or malicious supplying, or ad-

ministering to a pregnant woman, or causing or procuring to be taken by her, any drug, poison, substance or noxious thing, or unlawfully using or causing to be used any instrument or other method whatsoever, with intent to procure or cause an abortion."

The statutes on this subject recognize the right of a physician to produce an abortion in the interest of the mother. The question arises: Should this right be exercised? Without undertaking to discuss the various conditions under which the exercise of this right might be considered, the broad proposition is laid down that the occasions on which it would become imperative to sacrifice the life of the child to save that of the mother are extremely rare. With the two great resources of rectal alimentation and Cesarean section at command, it is believed that practically every pregnancy can be safely carried to a point at which the life of the child may be saved. The methods and means of maintaining nutrition by rectal alimentation have been so perfected that the production of abortion, or of premature delivery, for gravid nausea should rarely or never be required. At all events, by this resource the woman ought to be carried to the point of certain viability of the child before premature delivery is resorted to. For deformed pelvis surgery, with its tremendous advances in skill and technique, offers in Cesarean section a resource for saving the life of the child, and at the same time of jeopardizing to such a small degree that of the mother, that it should be universally employed in such cases. Dr. L. L. Hill, a surgeon of distinction in my state, and fully informed on these questions, furnished me recently the following statistics applying to Cesarean section: "1. Zweifel performed 76 Cesarean sections with 1 death. (J. Whitridge Williams, professor of obstetrics in the Johns Hopkins University, 1903.) 2. In 1903 J. Whitridge Williams collected the reports of 335 cases of Cesarean section by various operators, with a mortality of 6.87 per cent. 3. Not a single death of a mother occurred in 11 Cesarean sections recently performed at Johns Hopkins Hospital. 4. The mortality in Cesarean section should be about the same as that resulting from operations for simple ovarian tumor."

Without pursuing this discussion further, I submit to this Section the following propositions, and invite an expression of judgment thereon, not only by the individual members, but by the body:

1. The conjunction of male and female germs constitutes, from a scientific standpoint, birth.
2. The term conception should be abolished and that of birth substituted therefor.
3. In dealing with all stages of pregnancy, even the earliest, physicians should realize the extreme gravity of the condition, and should never condemn to death a fetus, however young, without the maturest consideration, and without calling to their aid the highest professional authority within reach; in a word, without carrying the case to the nearest and wisest medical supreme court accessible.
4. The principles herein contended for should be impressed on the members of the profession, taught to medical students and promulgated widely among the people.
5. Medical men should interest themselves to see that the statutes of their respective states are ample for the protection of the *fetus in utero*.

DISCUSSION.

DR. H. O. MARCY, Boston, said that his opinions correspond with those of Dr. Sanders. He believes that the conclusions

should be emphasized most positively. A physician may induce an abortion because he believes that the life of the mother is more valuable than the life of the fetus, but he should try to conserve the life of both to the best of his ability.

Dr. W. H. SANDERS declared that it was not stated in the paper that abortion should never be brought about, but that it should be the result of very mature consideration and after consultation with the highest and wisest and most experienced authorities within reach.

STUDIES IN ROENTGEN RAY DIAGNOSIS OF CHEST DISEASES.

JAMES E. TALLEY, M.D.

AND

WILLIAM S. NEWCOMET, M.D.

PHILADELPHIA.

I.

The use of the Roentgen ray as an aid in the diagnosis of chest diseases has by no means received the attention that it justly merits. No doubt its neglect has been principally due to the fact that the expense is still a factor, and at the same time the danger from burns, which lately has been so grossly magnified, has deterred many who would have otherwise given their sanction, if not direct co-operation.

When the x-ray first came to be used, it seemed as if it was to be generally adopted for routine examinations in diseases of the chest, mainly through the use of the fluoroscope, but during the excitement many methods of examination were advised that consisted of so much detail that it served more to repel than to at-

tract those who were only passively interested. For instance, methods were advised to measure the density of pulmonary consolidations by such means as graduated metal scales, of different sorts, i. e., one layer of metal superimposed on another, different thicknesses of wire, or different sized perforations in a sheet of metal, and it was soon found that the personal equation was such a great factor that, generally speaking, they were found to be useless, and we hear very little about them. Besides the element of personal equation, other facts entered into the cause of error by the use of such apparatus.

The fluoroscope itself was soon found to be a rather fickle instrument. This was caused in the most part by its degeneration, or variation in the salt from day to day. At the same time the variation of the x-ray tube, darkness of the room, the length of time the examiner has allowed his eyes to become accustomed to the darkness, etc., all enter into the cause of error, if not most minutely considered.

But as this field became more developed, it was found that the minute definitions were best studied from the radiograph, and these must be made by an exposure of a few seconds, or else the movements of the chest will destroy all that is to be gained. These are best made without the use of intensifying screens, as they also tend to destroy detail.

Previous to the introduction of these rapid plates it was found that we could study greater detail in the chest with the fluoroscope, and at the same time it was well known that it was an easy matter to overlook a fracture of a bone with this same instrument; this was easily explained by the fact that the fluoroscope lacks minute definition, and when it was necessary to expose a chest five or ten minutes for a picture we obtained even less detail. Yet the fluoroscope still has some use, for even from the best plates, with all possible technical imperfections eliminated, we are unable to study the movements of the different organs and their modifications in disease; at the same time we can not obtain a view of the parts from several different positions in rapid succession, and these points alone open up a field which give a great degree of usefulness.

The objection to the use of the fluoroscope is the risk of burn, and this must be carefully considered and the greatest precaution must be taken for both patient and physician. The former is likely to be given an acute burn, which is by no means agreeable, while the latter is more likely to suffer from what might be termed a chronic burn, which is more insidious and less active, though in the end the result is likely to last a lifetime, if not to terminate the existence of the individual.

To obviate this accident, we have devised a simple screen for the protection of the operator, and at the same time it is used as a recording apparatus. The screen is made of wood in three sections, each section about 24 inches wide and 6 feet high. These hinge together with the ordinary L hinges, so they can be taken apart for convenience and stored. Each section is made to hook rigidly at right angles with its fellow; thus if a fourth side was added it would form a square-shaped pyramid. By leaving one side open the patient can easily be placed in position or removed as desired. Two sides of the screen are covered with metal; thin sheet lead is best. In one is a movable window for the fluoroscope; and it might be here stated that the fluoroscope should be large enough to give a shadow of the whole chest without being moved. Small fluoroscopes

are useless and even dangerous. The third side is not covered with metal, but simply with black paper to enclose the x-ray tube and thereby lessen the light in the room, and at the same time to act as a frame for measurements and plumb lines used for centering the x-ray tube. The fact that no metal is on this side lessens the danger for puncture. The side directly opposite has the frame for the fluoroscope adjustable for different positions, depending on the patient's condition. Over the fluoroscope is placed a piece of plate glass, which is transparent to light rays, but blocks the x-ray to a great extent. At the same time it serves another purpose, in protecting the screen from being scratched by the point of the pantograph, which is used for recording the conditions as they exist. The pantograph is firmly attached to the same side of the screen on a soft piece of wood, so that paper can be easily placed under the pencil by a few thumb tacks. The tracing on the glass over the fluoroscope will be thus easily recorded, about one-sixth its natural size, which is very convenient for records. It is best to have this instrument attached to the side, not to the protecting connecting side, as it will lessen the danger of the operator's coming in the range of the active ray.

To minimize the amount of danger to the patient a cardinal rule must be adopted not to expose the body to the ray longer than is consistent with a thorough examination and not to re-examine at too close range; second, to use only enough energy to penetrate the body, which is much less in a dark room than in one only semi-dark, and at the same time the eye must be accustomed to the darkness; third, to keep the x-ray tube at least a foot from the body, and 18 inches is still better. Besides lessening the danger of burn, there is also less distortion of the shadows on the screen. Unfortunately, in heavy subjects it will be found that 18 inches is too far away for a good penetration. The use of a large fluoroscope that will cover the whole chest is here again explained.

II.

Though we have examined a considerable series of cases, a large proportion of which Dr. Musser has put at our disposal from both his ward and his private practice at the Presbyterian Hospital, we do not claim to add anything to the general principles and findings as set forth by others in the same field. We simply wish to add our testimony as to the usefulness of this means of diagnosis in thoracic diseases, to mention our simple means of securing records of fluoroscopic shadows, which Dr. Newcomet has described and pictured above, and to refer to a few cases where this method has shown its superiority either in point of time or precision, or both.

The drawbacks to the fluoroscopic work are the necessity of doing it at night to insure a sufficiently dark room, and the pavilion system of hospital construction, which renders difficult or impossible the examination of many acutely ill patients. The Roentgen examination must be considered a supplementary means of diagnosis and its findings interpreted solely in connection with the data obtained by the history and all other means at our disposal. For instance, a shadow showing involvement of a part of one lung may mean tuberculosis, pneumonia, pleurisy, loculated effusion or new growth, and only the history of the case and the other means of diagnosis enable us to say definitely which it is. Thus used, it will put inspection on a level at least with percussion in pulmonary disease. In fact, inspection,

as represented by both fluoroscope and skiagraph, when brought into direct contrast with percussion, in many conditions appears to us to have a decided advantage. It is but the outcome of the higher development of the sense of sight, as compared with the sense of touch, in the ordinary individual. A pneumonia or tuberculosis beginning deep in the chest may be revealed by the x-ray examination before other signs and symptoms are conclusive. A not infrequent type of case is like the following: A woman of 30, anemic looking, troubled with cough and recurring diarrhea, was examined by us. Her general appearance, the cough and the family history strongly suggested tuberculosis, but there was no sputum in which to seek tubercle bacilli and no evening fever. A systematic examination of the chest on two occasions by the ordinary means gave no satisfactory evidence of consolidation, and it seemed necessary to accept the enteritis as probably the only cause of the trouble so far; but it failed to explain the cough satisfactorily. The Roentgen examination with the screen at first showed only a suspicion of a darkening at the level of the inferior angle of the left scapula. Three weeks later, on her return from an outing, this area had increased and was now recognizable by compression and auscultation. In her case the x-ray gave a clue to the spot on which to center the attention before the examiner had been keen enough to light on it by other means.

About a year ago, when typhoid was rather prevalent, a girl of about 18, whose mother had a fibroid process in one lung and whose brother had had incipient tuberculosis, developed a moderate fever after feeling more or less ill for two weeks. A quick and definite decision was imperative, as a journey to the South Pacific had been arranged and the time for sailing was at hand. All known means of differential diagnosis were used except the Roentgen, which, in the light of later experience, would probably have been the most useful. Largely because of the strong family predisposition and the failure of any further typhoidal symptoms to develop, she was allowed to sail. On her return, as she had not gained, and as the right upper lobe now showed slight jerky inspiration, she was subjected to the Roentgen examination. The number of enlarged lymph glands lying beside the middle shadow, which were evident even on the screen, showed at once where the trouble was from the first, and had we used the x-rays at that time we should probably have sent her off with less misgiving. In fact, the detection of enlarged mediastinal glands has seemed to us one of the most useful provinces of the x-ray. In children it is specially applicable because of their thin chests, though we have used both skiagraph and skiagram successfully and frequently with adults. In no class of cases has it served us better than in making an early diagnosis of secondary involvement of the mediastinal glands coming on after the removal of the breast for carcinoma. Within a few weeks in two quite corpulent women, each of whom had a breast removed less than two years ago, by means of skiagrams, we have been able to give a positive diagnosis at a time when the only symptoms were apprehensive nervousness, some pain and slight dyspnea. That we were right the further history is unfolding. At present one case has some facial cyanosis, and the glands of the other are evident to percussion now that we know where to seek most carefully. In Hodgkin's disease we have been able to detect by both screen and skiagram the continuation of the enlarged glands of the neck into the thorax.

As said before, in acute diseases like pneumonia, we have not been able to examine cases as a routine measure. However, a method which presents to the eye both the shadow and the extent of consolidation both before and long after it is discernible by auscultation and percussion, and which alone shows the impaired movement of the diaphragm, is specially serviceable in atypical cases like central and senile pneumonia.

In pleurisy with effusion, the revelation to the eye of the dark shadow with its movable level, the displaced heart and the blotted-out diaphragm on the affected side, must add precision to the diagnosis.

Dr. John M. McLean has very kindly just furnished us a case of new growth of the thorax in a young man for examination. The case had been diagnosed by several physicians at first as pleurisy with effusion, as the signs were typical of that condition. The Roentgen examination gives a picture like a large effusion, with wide displacement of the heart. Two points differentiate it from diffusion. First, at rest the dark shadow at the right continuous with the heart gradually decreases in density toward the left. Second, on full inspiration the mass lights up irregularly, one or two areas being quite translucent.

As an example of the usefulness of this method in the exact location of pathologic lesions, we may cite a case of interlobar empyema following pneumonia, which we were able definitely to locate as lying posteriorly between the right upper and lower lobes.

Nowhere does the screen give livelier satisfaction than in the study of the heart and great vessels of the thorax. Here the fluoroscope shows the living, pulsating organ, while the skiagraph reminds one of a composite photograph, the sharpness of outline being lost because of the movement of pulsation. This is lessened in the instantaneous skiagraph, but the screen alone will show us the moving heart. The shape, size and position of the heart we have been able to determine by the skiagraph in at least two cases where the muscular development was so tremendous as to prevent entirely the casting of a sufficiently distinct image in the screen. In these cases, both men, the marked muscularity as well as fat, made percussion and even auscultation of comparatively little use. The absence of shadows suggestive of aneurism, and the normal position of the heart, with greatly increased transverse diameter, taken in connection with the history of the case, made dilatation due to excessive exercise the most probable explanation of the dyspnea and arrhythmia. The examination of the heart by the screen after outlining it by percussion shows the relative limitation of percussion and reveals the greater accuracy of the outline made by the pantographic arrangement above described. Since the heart lies comparatively near the screen, the shadow is relatively accurate, and any increase or decrease in size or change in position can easily be recorded by pantographic tracings at intervals, the technique being constant.

A neurotic young woman from Dr. Mitchell's service was referred to us for examination by Dr. Cornell. There was a history of spells of dyspnea at intervals, which seemed too genuine to be considered simply hysterical. The heart when examined by the usual methods showed only a pulmonic systolic murmur, which was considered functional. There was nothing in the pulmonary, cardiac, renal or blood examinations to explain the attacks. The fluoroscope showed the small-

est heart that we have ever seen in a woman of her weight and physique. Evidently it was a case of congenital hypoplasia. There was enough cardiac energy for existence, but no reserve for the requirements of an ordinarily active life. That anyone would have diagnosed the condition satisfactorily by percussion we doubt. The form of the heart in the organic lesion takes a certain type in one's mind. The wider transverse diameter of the mitral lesions and the elongated shadow of the aortic lesion are really reducible to definite diagrams. The constant darkening of the pulmonary reflex in mitral disease as compared with aortic disease is a diagnostic point between the two conditions. The obstructed pulmonary circulation is the cause. The distended right auricle would come into prominence more often were it not for the fact that in just the conditions where it is most overfilled (except emphysema) the pulmonary shadow is deepest and obscures the auricle. A rather thin boy of ten years afforded us the most prominent left auricle that we have seen. The lesion was evidently mitral insufficiency, but the fullness of the left auricle and the depth of the sulcus between auricle and ventricle we had never seen so marked before both in skiagraph and on the screen. A natural deviation of the heart, as well as an over-filled auricle must have been the explanation, as in mitral disease ordinarily no such marked auricular shadow was seen. Changes in position of the heart could not be better demonstrated than in some four cases of mitral diseases with secondary tricuspid insufficiency and enlarged left lobe of the liver. The lateral enlargement of the heart was conspicuous, but the wide change toward a horizontal position supported by the diaphragm and left lobe was remarkable. That the so-called apex could be so far displaced as to cause a diffuse pulsation well up toward the axilla and beyond the anterior axillary line could be understood when a goodly part of the left ventricle was seen to strike the thorax wall at each beat. With the recovery of compensation under rest and digitalis the heart assumed again more nearly the vertical position on full inspiration.

The number of aneurisms at our disposal has been small, but their fluoroscopic study helpful. In at least two cases we have noted an unusual projection to the left of the descending part of the arch of the aorta. They suggested dilatation of the aorta or small aneurisms, though there were no reasons for suspecting either. In one case the thorax was normal, in the other there was fibroid tuberculosis of the right upper lobe. A possible explanation is that the solidified lung offered less opportunity for the vessels to sink into its substance in inspiration. They interested us as illustrating that the part of the descending aorta visible on the screen varies, and one should not be misled into pronouncing such variations aneurisms. In a case of aneurism of the descending aorta there was enough enlargement of outline in pulsation to differentiate it from other possible consolidations, as enlarged glands. The skiagraph was better in detail, but of course could show no pulsation. In case of complete coagulation in the sac the simple movement due to pulsation without enlargement of outline in the shadow makes it difficult, if not impossible, to say decisively whether one is dealing with an aneurism or some other solid body, as an enlarged gland. In such cases the image is helpful, and the differential diagnosis, as before emphasized, must rest on the entire findings of the case.

An aneurism apparently beginning in the innominate

and involving the subclavian was shown by the skiagraph more conclusively than could have been done by percussion, to involve the aorta proper, thus putting operation out of the question.

In conclusion, we believe that a method that is rarely, if ever, inferior to other methods, usually at least equal to them and sometimes superior, is bound to have a wider recognition and use than at present.

THE EFFECTS OF OSMIC ACID INJECTIONS.

JOSEPH RILUS EASTMAN, A.M., M.D.

INDIANAPOLIS.

Billroth and Neuber¹ were the first to employ osmic acid for neuralgia. They used repeated injections by puncture through the skin without exposure of the nerve; as many as twenty injections were given in some cases. Eulenburg,² employing a similar method, had good results in only 3 out of 13 cases, which included neuralgias of the brachial, sciatic and trigeminal nerves. Schapiro,³ who used a 1 per cent. solution of osmic acid in glycerin and water, records 5 successes out of 8 cases at periods of two to six months after injection. Jacoby⁴ claims 8 cases of cure out of 18 sciaticas, and warns us that it is "dangerous to implicate a motor nerve." Cohen⁵ of Philadelphia used repeated injections (without exposure) into the sciatic nerve, using as much as 30 minims of a 1 per cent. solution. Ellis⁶ records the occurrence of some irritation after injection into a thumb in which pain followed a sprain. Mercer⁷ injected deeply and repeatedly into the sciatic region, with temporary relief and no ill effects. Franck⁸ obtained three successes by direct injection. Turner⁹ records a case of trigeminal neuralgia of two years' standing in which he injected into the infraorbital and after ten days relief followed, lasting six months, i. e., to the date when the patient was last seen.

Wright⁴ claims that most surgeons who have used osmic acid have injected it more or less at random without exposing the nerve trunk. He further states that such a method is quite sufficient to account for irregular and defective results and that it is also remarkable that so little is said of any ill effects, considering the very marked changes that osmic acid produces in the tissues, as shown experimentally by Frankel and as seen by himself in a case in which he used injections, and which, on removal of a portion of muscle which had been attacked by the acid, showed marked degenerative myositis. In all his cases Wright had exposed the nerve and had injected a 1.5 or 2 per cent. watery solution into the trunk or into branches; sometimes the injection had been both toward the periphery and toward the center, and the acid had generally escaped more or less freely into the tissues immediately around the nerve. Most of this author's cases were much too recent to justify any conclusion as to the permanent value of the method. He contends that it is impossible to eliminate the effect of the exposure and the mechanical results of manipulation and puncture of the nerve and of occasional unintentional section by the trephine.

He deems it clear that if this method is employed, the nerve should be fully exposed and not merely a

chance injection made through the skin. Immediate results in his cases as regards both harmlessness and at least temporary relief quite justify the use of the plan before resorting to any such severe procedure as excision of the Gasserian ganglion. He preferred to expose and inject the trunk in some cases rather than to deal with the terminals only; and this is a matter that should be settled, since the severity of the one procedure is of course much greater than that of the other. It is also of importance to remember that delay in relief may occur; i. e., that pain may continue for some days or even longer after the injection and then pass off. So that it is not necessary to assume failure or to repeat the operation until time has been given to make sure that it is necessary.

Wright⁸ reports a case of a male, aged 33, who suffered for three years with pain in the testes. The right testis was removed, after which pain persisted in the left testis and cord. Osmic acid was injected into the tissues of the cord, with improvement. In another case, that of a male, aged 31, a postman, there was pain in the left heel, interfering with walking. The posterior tibial nerve was injected with osmic acid. The result was a failure. Wright several times injected the lingual and inferior dental nerve after prepping the lower jaw, with indifferent results. In the majority of these cases, there was return of pain after, at most, a few months. He secured temporary relief by injecting a 2 per cent. solution of osmic acid into the auriculotemporal nerve.

Up to November, 1899, W. H. Bennett⁹ had treated 12 cases of neuralgia, involving various nerve trunks, by injections of a 1 per cent. solution, using 10 to 12 minims for each nerve trunk. The symptoms were relieved in a few hours and in all cases the cure seemed to be complete. In Bennett's cases the median, popliteal, peroneal, and the branches of the trigeminal nerve were injected. Bennett believes that the results will be better if the injections of osmic acid be applied early in the course of the disease.

In a personal letter to Dr. J. B. Murphy,¹⁰ Bennett reviews 8 additional cases, making 20 in all. Of these 20 cases, 18 experienced complete relief. The time elapsing between operation and report, however, was, it should be noted, in several cases, very short.

Murphy¹¹ reported 14 cases in which osmic acid was injected, in a 1 to 2 per cent. solution, into nerve trunks for neuralgia. He found that the injections relieved the pain immediately and for a long period of time. He advised against injection into the superficial tissue for peripheral neuralgia, as the nerve trunks were easily located. He advised also against injection into a motor nerve or a motor nerve area and, therefore, never into a spinal nerve except in amputation stumps. Murphy found local necrosis of tissue about the injected nerve and even the wall of the foramen showed necrotic changes occasionally. The necrosis did not suppurate except in cases exposed to marked infection. In *tic douloureux* he advocates injection into all branches, including the palatine, lingual, mandibular, supra-orbital and infra-orbital. He calls attention to the fact that there may be two or three divisions of the supra-orbital and that each should be searched for and injected separately. He advises the use of a general anesthetic.

Judging theoretically from experience in resections

and ganglion operations, Murphy believes that the relief will not be permanent after the injection of osmic acid. Clinical experience up to date, however, particularly the experience of Mr. Bennett and himself, leads him to believe that many cases are really permanently cured. While he admits that time alone can determine the final results, he commends the injection of osmic acid because of its ease of application, its *nil* mortality and its immediate results. Murphy reports no injections of osmic acid for conditions other than *tic douloureux*. In these cases he injected osmic acid in a solution of 1 to 2 per cent., 10 minims into each trunk.

AUTHOR'S CASES.

I have injected osmic acid for neuralgia eleven times in nine patients, as follows:

CASE 1.—*History*.—Mrs. W., aged 71 years, was first seen on July 12, 1904. The case was one of typical intense *tic douloureux* involving the right side of the face. The first paroxysm occurred about ten years previously; subsequent attacks gradually becoming more frequent and more severe. Practically all of the many remedies recommended for the relief of this condition had been tried without benefit. For almost three months prior to the operation the pain had been excruciating, the attacks occurring with exhausting frequency. The whole right side of the face was exquisitely tender, particularly in the neighborhood of the infra-orbital and mental foramina. The tongue was sore and tender at all times, thus greatly interfering with speech. During attacks the pain most acute about the right angle of the mouth and the angle of the right jaw. Violent spasm of the buccinator was almost constantly present during the attacks.

Treatment.—A 2 per cent. solution of osmic acid was injected into the supra-orbital, infra-orbital and inferior dental nerves at the supra-orbital notch and the infra-orbital and mental foramina. The manner of operation was that practiced by Murphy. Ten drops of a 2 per cent. solution of the osmic acid were injected into each branch and two or three drops were forced into the perineurial fat of each foramen around the nerve. At the time of the injection of the osmic acid the nerves were drawn with very slight force from the foramina and held during the injection, but the trunks were not stretched as in the operation of neurectasy.

Result.—Up to the present time there has been no return of the pain since its abatement one week after the operation. During the first week several rather severe paroxysms occurred, these gradually decreasing in severity.

Urinalysis.—An interesting feature of the case was the nephritis occasioned by the elimination of the acid. The urine passed during the first twelve hours succeeding the operation showed nothing unusual; on the second day, however, nephritis resulted. There were no symptoms, either subjective or objective, pointing to its onset or presence, excepting the appearance of and findings in the urine. The patient did not complain of pain in the loins. Urine passed thirty-six hours after the operation showed the following: Reaction, very slightly acid; sp. gr. 1.036; color, dark claret. The specimen was centrifugated and the sediment composed a little over a quarter of the volume. The clear fluid above the sediment was light claret in color, the sediment being dark red. Examination of the fluid portion showed a small amount of albumin, with no sugar, bile or other abnormal substance present. Examination of the sediment showed it to be composed almost entirely of red blood cells. There were no casts, epithelial cells or pus cells. The red blood cells disappeared from the urine on the fourth day.

CASE 2.—*History*.—Miss L., aged 22, had suffered pain, paroxysmal in character, for four or five years. Only the area supplied by the inferior dental branch was involved. Paroxysms had increased in frequency during the last few weeks before operation until the pain was almost continuous, and the region of the lower jaw on the right side was very tender.

Treatment.—On Oct. 10, 1904, ten drops of a 2 per cent. solution of osmic acid were injected into the trunk of the

11. *Journal A. M. A.*, Oct. 8, 1904.

inferior dental nerve at the mental foramen, and a few drops were forced into the perineurial fat around the nerve.

Result.—Pain persisted for two weeks after injection and then abated and up to the present time has not returned.

CASE 3.—History.—Mr. B., aged 27, had had sharp pain for eighteen months in the area supplied by the supra-orbital and auriculotemporal branches. The superior maxillary and inferior dental trunks were not involved.

Treatment.—Open operation was refused and twenty drops of a 2 per cent. solution of osmic acid were injected subcutaneously along the course of the trunk and branches of the auriculotemporal nerve. Ten drops of a 2 per cent. solution were also injected at the supra-orbital notch.

Result.—There was almost complete relief from pain for a period of two months, after which the pain recurred, somewhat reduced in severity.

CASE 4.—History.—Mrs. S., aged 41, had had violent pain in the area supplied by the inferior dental and infra-orbital branches for eight years, the paroxysms gradually increasing in severity and in frequency.

Treatment.—On Feb. 15, 1905, ten drops of a 2 per cent. solution were injected into the involved trunks at their respective foramina.

Result.—Pain persisted in both regions without much abatement for ten days, after which it gradually disappeared and had not returned when patient died three months later of cerebral hemorrhage. There was no autopsy.

CASE 5.—History.—Mrs. H., aged 70 years, exhibited intense tic douloureux involving the right side of the face, the first attack having occurred twenty years previously, subsequent attacks gradually increasing in severity and in frequency.

Treatment.—On July 5, 1904, a 2 per cent. solution of osmic acid was injected into the supra-orbital, infra-orbital and inferior dental nerves at their respective superficial foramina of exit. Ten drops of a 2 per cent. solution were injected into each branch and a few drops spilled on the perineurial fat.

Result.—The pain persisted for two weeks, after which it abated and did not reappear until the following July one year later, at which time the pain appeared in the area supplied by the inferior dental branch only. Under cocaine anesthesia ten drops of a 2 per cent. solution of osmic acid were now introduced through a hypodermic needle directly into the large mental foramen, without incision, with the result that the pain disappeared for ten days, at the end of which time it reappeared in this branch. An incision was then made and the trunk injected, the pain continuing for one week, after which it practically ceased. The last operation in this case was done on July 25, 1905.

CASE 6.—History.—Mr. J., 55 years old, had suffered for about ten years with sciatic neuralgia and had tried all the more common medicinal methods of treatment of this disease.

Treatment.—Osmic acid in a 2 per cent. solution was injected subcutaneously at three points along the course of the sciatic nerve on two occasions, one month apart.

Result.—Each time there was slight temporary benefit. The effect was no more pronounced and no more lasting than that which had been produced by injections of them in two-grain doses in a similar manner in the same case.

CASE 7.—History.—Mrs. C., 35 years old, suffered with neuralgia, implicating the infra-orbital and auriculotemporal branches.

Treatment.—On March 12, 1904, osmic acid, 2 per cent. solution, was injected, ten drops over the infra-orbital foramen and ten drops subcutaneously in the area supplied by the auriculotemporal nerve.

Result.—Partial relief, lasting to the present time.

Cases 8 and 9 were simple subcutaneous injections of osmic acid, 2 per cent. solution, under cocaine anesthesia. The injection, in each instance, was into the infra-orbital and mental foramen. The results were unsatisfactory.

CHANGES PRODUCED IN THE TISSUES BY OSMIC ACID.

Frankel¹² of Hamburg found, experimentally in animals, degeneration of axis cylinders and degeneration of

white substance with epineuritis and myositis as the result of his injections.

Murphy found, on microscopic examination, the most important changes at and distal to the point of injection. The degree of pathologic alteration varied to a considerable extent, dependent on the thoroughness of the injection and whether infection had resulted. At the point of injection there was always more or less staining of the perineurial and interstitial fat with the osmic acid. There was marked derangement of the fibers. The inflammatory reaction was always less extensive than might naturally be expected. An occasional area of focal necrosis, a few foci of round-cell infiltration, and here and there a leucocyte, attracted thither by the foreign substance, were all that was to be noted.

Distal to the point of injection the nerve trunk, in some cases, seemed atrophic, but there was no interstitial changes. Proximally, no changes were to be found except in the immediate vicinity of the injection. At and distal to the point of injection, there was more or less extensive fatty degeneration of the myelin sheath. This varied in amount from the involvement of all the fibers to degeneration of an occasional fiber only. Proximally, the myelin sheath was unaffected except immediately above the limit of blackening, which was the means of defining the extent of the injected area.

INVESTIGATION¹³ INTO THE NATURE OF THE TISSUE CHANGES PRODUCED BY OSMIC ACID.

EXPERIMENT 1.—Adult rabbit.

April 2, 1905.—Injected into deep tissues of left hind leg five drops of a 2 per cent. solution of osmic acid freshly prepared. Rabbit allowed to go free ten days. No paralysis developed. No clinical changes.

April 13.—Exposed left sciatic nerve and injected five drops of a 2 per cent. solution osmic acid directly into substance of nerve. Nerve and surrounding structures blackened. Skin incision closed with catgut sutures.

April 15.—Paralysis developed, which continued until rabbit was killed.

April 26.—Chloroformed.

EXPERIMENT 2.—Puppy, four months old.

August 13.—Injected left sciatic nerve with a 2 per cent. solution freshly prepared osmic acid. Five drops injected with very little loss of acid into surrounding structures. Nerve at once blackened by acid. Suture closed by catgut.

August 15.—Paralysis developed. Dog carried foot.

August 18.—Paralysis improved.

August 20.—Paralysis practically disappeared. Nutrition good.

August 20.—Dog killed by chloroform.

EXPERIMENT 3.—Small rabbit, three months old.

August 14.—Injected both sciatic nerves with a 2 per cent. solution of osmic acid, using five drops to each nerve. Some acid lost in surrounding tissues. Nerves and surrounding tissues blackened by acid at time of injection.

August 15.—Paralysis of both legs.

August 17.—Continued paralysis. Rabbit dragged legs. Nutrition poor.

August 18.—Rabbit died with paralysis persistent. Wounds not infected.

EXPERIMENT 4.—Adult rabbit.

August 14.—Left sciatic nerve injected with a 2 per cent. solution osmic acid. Nerve and surrounding tissues blackened.

August 16.—Paralysis developed.

August 18.—Paralysis continued. Sutures catgut still in situ. Wound infected.

August 20.—Rabbit killed by chloroform.

EXPERIMENT 5.—Large rabbit.

¹² Made, under the author's directions, by Dr. Everett E. Padgett.

August 13.—Injected both left sciatic nerves and cords of right brachial plexus with a 2 per cent. solution of osmic acid, using five drops in each injection. Skin sutured with catgut.

August 15.—Developed slight paralysis of left hind leg, which improved before rabbit was killed. No paralysis in fore leg.

August 20.—Rabbit killed by chloroform.

EXPERIMENT 6.—Large rabbit.

August 20.—Injected both sciatic nerves and also deep muscles of fore leg with a 2 per cent. solution of osmic acid. Wounds closed with catgut. Nerves blackened.

August 23.—Paralysis of both hind legs. No paralysis of fore legs. Wound on left hind leg infected.

POSTMORTEM, GROSS AND MICROSCOPIC EXAMINATIONS.—Parts of tissue were removed from the various organs, hardened in formalin, and stained after the following methods:

A. GENERAL STAINS.—1. Hematoxylin and eosin, the eosin being very heavy. 2. Borax carmine. 3. Van Gieson.

B. SPECIAL STAINS.—1. Nerves. *a*. Myelin sheath stains, aa. Paul Weigert's. *b*. Stain for neuroglia fibers. *bb*. Phosphotungstic-acid hematoxylin.

OTHER ORGANS.

In the brain the corpora quadrigemina; the medulla oblongata and the cerebral cortex were normal. The heart and liver were normal. In the muscles at the site of injection the tissues were dark; the nuclei, clearly visible; the sheath of muscle fibers, visible; the protoplasm, stained poorly, the different parts could not be made out; inflammatory changes were present. The tendons showed inflammatory changes.

CONCLUSIONS.

1. The injection of 10 drops of osmic acid in 2 per cent. solution into sensory nerve trunks is safe. The likelihood of irritation of the kidney, however, should not be forgotten in cases exhibiting kidney lesions. It is not probable that the death from cerebral hemorrhage three months after injection of the acid was due in any sense to the injection.

2. Injections into the inferior dental or other nerves should be made through the month, since infection of the wound and necrosis may result, with consequent failure in the action of the acid.

3. Immediate relief should not always be expected, notwithstanding the cases of Bennett and Murphy were all immediately relieved. No one of my cases, even those in which the acid was accurately injected into the nerve trunks and into the perineurial fat, was promptly relieved, relief coming in from one to two weeks. The observations on this point of Wright, who had a large experience with osmic acid injections, correspond to mine.

4. There is very little doubt that the stretching of the nerve trunk, necessarily incident to the injection, is productive of good, supplementing, as it must, the action of the acid. There is, therefore, no good reason why the stretching should be avoided intentionally, except perhaps for experimentation.

5. In the case of small nerves, it will be found exceedingly difficult to inject directly into the nerve trunk, that is, the needle eye will pass to the distal side of the thread-like nerve, or perhaps not enter the nerve substance at all. Or, notwithstanding the utmost care, the fibers may be so teased apart by the needle point that the fluid will simply be spilt about the nerve. In such a case, in order to bring the acid in contact with all of the fibers, it is wise to clip the nerve so that the end may be bathed in the fluid.

6. The effect of manipulation of the nerve, as by stretching, has not as yet been eliminated as a possible aid to the chemical action of the osmic acid; therefore, a general anesthetic should be administered so that neurotomy or section of the nerve may be done if desired.

7. My experiments have shown no changes in the nerve tissues as the result of injections of osmic acid other than the disintegration of fat and oil globules in the perineurial space and in the white matter of Schwann, such white matter of Schwann being simply fatty matter in a fluid state insulating and protecting the essential part of the nerve. The degenerations appearing in the nerve itself are only such as may be fairly attributed to nutritional changes and exposure, the indirect result of the selective action of osmic acid of destroying fat. There is no reason why this fat should not be restored and the nerve again become capable of transmitting sensation, that is, theoretically, the neuralgia may return after injections of osmic acid.

8. Osmic-acid injections are uncertain in effect as to the cure or relief of neuralgia.

9. A large percentage of cases of neuralgia will be relieved for months by osmic-acid injections.

10. The injection of osmic acid for the relief of tic douloureux is justifiable, even if it should become necessary to repeat the injections at intervals of a few months, particularly in view of the unfavorable results of the so-called radical operations.

11. The local irritation produced by the acid and the remote toxic and irritant effects are not serious in their consequences and have no meaning as to the effect of the osmic acid in relieving neuralgia.

12. The solution of osmic acid should be made fresh for each operation, as deterioration is rapid.

13. Pain persisting several days in a small circumscribed area means that the filaments supplying this area have not been acted on by the acid. The acid usually finally destroys such filaments. It may become necessary, however, to reopen a wound for the purpose of injecting such filaments.

14. Mere subcutaneous injections are of little or no value.

Value of Society Meetings.—The art of medicine is important, but in these days of scientific accuracy in diagnosis, the microscope and test-tube and x-ray, can not be ignored even by the busiest of men, as by their careful use mistakes are prevented and injustice to our clientele avoided. It is in journals and books and medical societies that knowledge and familiarity with what is now in medicine must be learned, and wise is the doctor who early discerns that a membership in an active medical association is one of the best means of keeping in touch with the best, both of science and of men, that is worth knowing in his profession.—A. W. Hurd, in *Buffalo Medical Journal*.

SOME STUDIES IN METABOLISM OF CANCER PATIENTS AS COMPARED WITH NORMAL INDIVIDUALS.

H. H. GLOSSER, M.D., AND W. S. FRISBIE, Ph.D.
BUFFALO, N. Y.

In this paper it is proposed to review and summarize previous work on nitrogen and chlorin metabolism, and then to give in detail experiments carried out, at the suggestion and under the direction of Dr. Clowes, on a normal individual and on several cancer patients, and to compare the results of such experiments.

SUMMARY OF THE PREVIOUS WORK.

Much of the previous work loses in value because of the lack of accurate data recording quantities of nitrogenous food and chlorids ingested, quantity of nitrogen and chlorids excreted through the feces, body weight, etc. One very important source of error in the determination of chlorids is the change from solid to liquid food, especially the substitution of a milk diet for the normal solid food. The ratio of chlorids to proteid matter in milk is smaller than in solid food as usually consumed; hence, with milk one expects a reduced chlorid ingestion and reduced chlorid excretion.

The literature for the last twenty-five years shows divergent views on the equilibrium of nitrogenous bodies and chlorids in cases of impaired metabolism. Vogel,¹ Rommelaire,² Jacoby³ and others noted marked disturbances in excretion of urea and chlorids in cachectic cancer patients, but did not carry out exact experiments to determine the amount of food stuff consumed as compared with the waste products excreted. Müller⁴ and Klemperer⁵ concluded that, under the influence of the toxic excretions from tumors, the amount of nitrogen excreted was in excess of the amount ingested, while Moraczewski finds the converse to be true. Similar differences of opinion exist as to the retention and excretion of chlorids.

A paper⁶ published by Jacoby in 1887 is one of the first records of work of real value. He compared the daily nitrogen excretion of a normal individual with that of a patient suffering from carcinoma of the liver, and found that, while the normal individual gained weight with a nitrogen excretion of less than 12 gms. daily, the cancer patient lost weight with an excretion of 18 gms. daily. The next work of value was done by Müller,⁴ who studied the conditions of metabolism in 9 cancer patients. He concluded that there was a continued loss of nitrogen from the system in spite of the rapid growth of the tumor, that the loss of body weight corresponded to the loss of nitrogen when the influence of edematous fluids was considered, and that where nutritive processes were seriously affected by the tumor the ratio of the nitrogen in the excreta to the nitrogen in the food was similar to that in starving individuals.

G. Klemperer⁵ concludes, from a series of fairly exact metabolic experiments, that when cancer and normal individuals are subject to the same experimental conditions

the former will lose and the latter may gain in body proteid.

Laudenheimer⁷ took five cancer patients and found that two maintained equilibrium of chlorids, while in two the chlorids excreted were below the amount ingested; he concluded that this was the result of nephritic or circulatory retention of water and salt.

Schöpp⁸ says that, while both chlorid and nitrogen excretion frequently fall below the amount assimilated in cancer patients, the difference may be attributed to ulceration of the tumor, the secretion containing considerable quantities of chlorid.

Böhne⁹ found in a marked cachectic cancer patient a daily retention of 3 to 4 gms. of chlorid for a period of four weeks, and further claims that a chemical analysis revealed four times the amount of chlorid normally found in the liver.

Braunstein¹⁰ carried out a series of analyses of urine in ten cancer patients, in five of which an exact record had been kept of the chlorid and nitrogen content of the diet. In three of the five patients a loss of nitrogen was observed, being particularly marked in a patient suffering from cancer of the esophagus, where the loss reached as much as 10.6 grams per day for a period of four days. He failed to find any marked difference between the chlorid contained in the food and in the excreta.

A review of this literature will impress one with the great variations in the results obtained. Some have observed a gain in nitrogen on the part of the system, which they attribute to the rapid growth of the tumor; others have noted a distinct loss of nitrogen, which they have supposed was due to the action of toxic substances produced in and excreted from the tumor. In any case, the discrepancies observed would justify further investigation in this direction.

While a diminished excretion of chlorids has frequently been observed in cancer patients, few of the early writers noted the fact that in many of the experiments, milk having been substituted for solid food which could not be assimilated, the chlorid ingestion was necessarily reduced. Therefore, it would be a wrong deduction to say that chlorids were retained.

A complete review of the literature bearing on this subject may be found in the Fifth Annual Report of the New York State Cancer Laboratory.

OBJECTS OF THIS STUDY.

The main objects of our investigations have been as follows:

1. To determine whether the gain or loss in weight of a cancer patient was associated with a corresponding gain or loss of nitrogen from the system and to compare these results with those obtained from the study of a normal individual.
2. To determine whether chlorid is retained in the system, by comparing the amount assimilated with the amount excreted, and, if so retained, to what extent.
3. To determine whether the chlorid retained in the system has any direct relationship with the supposed increase of chlorid in the blood and with the formation of edematous deposits.
4. To study the effect of adding or totally excluding chlorid from the diet as compared with the effect of such treatment on a normal individual.

METABOLISM EXPERIMENTS.

Case 1. Normal Individual.—In order to note the influence of varying quantities of chlorid on normal metabolism, it was determined to carry out a series of experiments on one of ourselves. For two periods of thirteen and nine days, respectively, experiments in feeding were carried out on Dr. G., physician, age 32, weight 66 kilo, health normal. During this time an accurate record was kept of all food and liquid consumed, and of all feces and urine passed and samples of food, liquid, feces and urine taken to the Gratwick Laboratory for accurate chemical analysis. Data were kept of daily weight and exercise. The first five days were devoted to determining the nitrogen equilibrium. It was found that body weight remained constant when the food ingested during twenty-four hours contained from 13 to 14 grams of nitrogen.

For the remainder of the period the amount of nitrogen was varied in quantity; this change, however, affected the body weight far less than the change in the quantity of chlorid. When the nitrogenous food was largely increased in quantity, a portion of the excess was passed by the bowel and the kidneys, the remainder being apparently retained by the system.

During the last two days of the first period the proteid food was reduced to a considerable extent, the results of which follow:

When the nitrogen ingested was reduced from 13.5 to 9.0 gms., the nitrogen excreted fell from 13.5 to 11.3 gms., whereas a further reduction to 5.1 gms. ingested led to an excretion of 9.3 gms. These figures show that a proportionate loss of nitrogen by the body follows a reduction of nitrogen in the food, but that the actual reduction in the excreta is only about one-half the actual reduction in the food.

During the second period constant body weight was maintained with an average daily consumption of 13.6 gms. nitrogen. A study of the last two days of this period, during which the patient was once more subject to partial starvation, shows that about the same ratio exists between the intake, output and loss of nitrogen, as in the previous starvation period. In other words, it became apparent that when the nitrogen of the food is rapidly reduced to a point below the normal, the loss on the part of the body required to compensate for this difference is not equal to the amount in question, but only to about one-half.

It was not deemed advisable to carry the reduction of nitrogen in the food beyond this point. The figures obtained indicate that the amount of nitrogen lost daily on a state of absolute starvation would be about 6 gms., or .1 gm. per kilo.

The study of the influence of varying quantities of sodium chlorid on elimination and body weight is very interesting. Under normal conditions the amount of sodium chlorid consumed lay between 7.5 and 8 gms. per day. When the ingestion of NaCl was increased from 8 to 27.6 gms. the total excretion was 20 gms., showing a gain of 7.6 gms. by the body. The following day the consumption of 22.9 gms. NaCl was followed by the excretion of 23.6 gms., a practical balance being established on this day. The next day, when 12 gms. only were consumed, a total of 17.6 gms. was eliminated, showing the tendency of the body to recover chlorid equilibrium, but the following day, when only 2 gms. were ingested and 9.5 gms. excreted, the body suffered a decided loss in chlorid, which was continued on the next day, when only 1.3 gms. being ingested 3.78 gms. were excreted. The following day ended the experiment with an ingestion of 9.2 gms. and a loss of 5.3 gms., showing a tendency of the system to replace chlorid previously lost. The results of chlorid experiments in the second period were very similar to those just mentioned.

The effect of large daily consumption of chlorid on the excretion of nitrogen is marked, the maximum excretion of nitrogen occurring at the same time as the maximum excretion of chlorid.

The curve representing body weight follows almost exactly the curve showing consumption of chlorid. The total loss of weight between the maximum and the minimum points, about 2 kilos, was accompanied by a loss of chlorid amounting to about 15 gms., which would fully account for that difference in weight, assuming that a .75 to .8 per cent. sodium chlorid solution is isotonic with the serum. The second period showed an even more exact ratio between chlorid ingested and body weight.

The loss of nitrogen during this period had an insignificant effect on the body weight as compared with the variation in chlorids.

The volume of water ingested shows a preponderance over that excreted by the kidneys of from 500 to 600 c.c. During the time when the greatest quantity of chlorid was ingested the intake of water was about two liters, while the urine passed was 1,300 c.c., the specific gravity never rising above 1023 to 1022. Only when the chlorid in the diet was reduced to a minimum did the urine excreted equal the water ingested.

We, therefore, see that the variations in body weight follow closely the variations in amount of chlorid ingested and excreted, the amount of water held in the system being directly affected by the amount of chlorid retained. A period of not longer than forty-eight hours is required to establish chlorid equilibrium, which is more readily effected than in pathologic cases.

Effect of variations in the amount of chlorid on other constituents of the urine: When the quantity of chlorid ingested was very high, there was a large volume of urine passed, a slight rise in nitrogen excretion, an increase in the phosphates, and a very large excess of uric acid, with a slight decrease in the ammonia. This excess of uric-acid excretion might be due to an increased destruction of nuclei of cells or a more complete removal of uric acid already existing in the blood. This latter theory is in accord with the results published by Dr. Clowes relating to the freezing point of urine, which indicate a probable relationship between the excretion of small ions and of large complexes, such as uric acid.

Case 2. Carcinoma of Pylorus.—J. W., age 75, weight 51 kilos. He experienced difficulty in taking food for months past; he became emaciated and cachectic. When

inspected and palpated a prominent tumor was revealed in the epigastrium. Autopsy showed carcinoma of pylorus.

Examinations were made of twenty-four-hour samples of urine and feces for a period of twelve weeks; for the last eight weeks preceding death estimation was made of total nitrogen and chlorid in the food in order to obtain a comparison of nitrogen and chlorid in food and excreta and to determine the influence of varying proportions of NaCl in the diet.

A glance at Table 2 shows that equilibrium in nitrogen and chlorid was maintained during the first two weeks, the body weight remaining constant. Then began a loss in nitrogen with a retention of chlorid, amounting during the last two weeks of life to 33.7 gms. of nitrogen lost and 22.8 gms. of NaCl retained, or 80 per cent. of

NaCl ingested was retained. During one week the ingestion of NaCl was increased to 17.8 gms. in the hope of eliminating chlorid, the products of metabolism and suboxidized products. The only result was increased edema on the part of the patient. A portion of the chlorid was undoubtedly retained in the system in the increased fluid of the body, but, unlike the normal individual cited, the kidneys did not pass off the excess of chlorid in from twenty-four to forty-eight hours. Possibly the retention of chlorid was due to new chlorid compounds formed by the suboxidized nitrogenous bodies.

March 26-Apr. 2.....	21.6	44.4	-22.8	8.5	1.5	+ 7.0

The patient received an average of 1.66 gms. NaCl per day, and he was unable to maintain equilibrium even with this very low ingestion. During the week when NaCl was increased to 17.8 gms., 15.8 gms. were retained in the system, the body weight going up to 1.25 kilos in spite of the loss of nitrogen, which was less marked than during other periods, probably due to retention of nitrogenous products in the edematous fluids.

This case, in which the N equilibrium of a patient weighing originally 51 kilos was maintained for a space of 14 days at 6.5 gms. and in which for the entire period of eight weeks, during which accurate observations were made, the average N excretion was only 6.7, affords further evidence in support of the work recently published by Professor Chittenden showing the possibility of maintaining a N equilibrium on a low amount of N for many months in a series of normal individuals.

When the interference with the nutrition caused by toxic or other influences resulting from the tumor are considered, it is remarkable that the loss of N suffered by the body should be as low as is frequently found to be the case in these and other similar series of experiments.

Case 3. Carcinoma of Esophagus and Liver.—Mr. U., aged 60, weight 75 kilos. The diagnosis was made during life and confirmed at autopsy by finding three inches of esophagus above the diaphragm a cancerous mass with metastasis to stomach and liver. The patient was fed through a fistulous opening.

For a period of six days exact analyses were carried out on the food to determine the nitrogen and chlorid equilibrium and the effect of increased and diminished feeding of NaCl.

Oct. 26-27.....	9.43	8.10	9.95	6.70	.52

A study of the accompanying table shows an average retention in the system of 1 gram of nitrogen daily, which may be explained by improvement in bodily nutritive processes or by the retention of nitrogen in the edematous fluids. Here, however, the retention was the same for both periods, while chlorid and water were retained only during the latter period.

During the first three-day period, when the consumption of chlorid was very low, the excretion of urine was high, averaging two liters per day, but when the chlorid consumption was increased the total volume of urine excreted was less than four liters, showing a retention of fluids and the production of edema. An estimation of the total chlorid ingested and excreted shows a tendency on the part of the system to retain a small portion of chlorid.

This patient, in the absence of marked toxic symptoms, showed practical equilibrium of nitrogen with a slight retention of chlorid.

Case 4. Carcinoma of Right Kidney.—Mr. T., aged 66. Autopsy revealed primary carcinoma of right kidney with secondary tumors in liver.

Total.....	40.9	61.4	19.2	3.59

For nine days preceding death exact chlorid and nitrogen determinations were made of food and excreta. A slight increase of chlorid for two days was not associated with any marked increase in the excretion of urine, but did cause edema and cachexia. A continued loss of nitrogen was noted in this case, and a strong tendency to retention of chlorid.

Case 5. Sarcoma.—Mr. C., aged 15. Sarcoma of skin and connective tissue in right epigastric region, having a maximum diameter of six inches. Patient refused operation and left the hospital at the completion of the feeding experiments covering twelve days. Accurate determinations of food were carried out on only two days, the remaining days being approximates.

*Approximately.

†Only traces, and so disregarded.

In this case, although a tumor existed and toxic symptoms were manifested, the patient retained a small amount of nitrogen, and the variations in the amount of chlorid excreted corresponded with the variations in body weight, as in the normal case already cited.

Case 6. Carcinoma of Vulva.—Mrs. N., aged 58. Tumor of right vulva, extending to vagina and cervix. Patient emaciated and cachectic.

Although experiments were carried out for forty-five days on the urine and twenty-four days on the food, only those of the last six days can be considered approximately correct. During this period there was a loss of 5.6 gms. of nitrogen and a gain of 1.9 gms. of chlorid which was scarcely comparable with a body loss of .75 kilo.

*Case 7. Cardio-spasmus.*¹¹—P. G., aged 59. Inability to swallow solid food. After a gastrostomy was performed he was fed through a tube for a fortnight. He subsequently died of pneumonia.

TABLE 7.

1	14.0	14.5		
2	13.6	10.4		
3	13.4	15.9		
4	13.9	13.3		

A series of nitrogen and chlorid determinations was carried out on this patient. During the first five days there was a decided loss of nitrogen, due possibly to the shock and the toxic effects of an infection which developed at the point of introduction of the tube. A subsequent determination of nitrogen showed a maintenance of equilibrium. The considerable loss of N in the first period attributable to the toxic influence of an infection

was far more marked than the loss of N due in other cases to cancer cachexia. There was no retention of chlorid to any extent, a fair equilibrium being maintained, and no edema being present.

Case 8. Stricture of Esophagus (supposed to be carcinomatous).—L. L., aged 44. In order to compare the nitrogen and chlorid metabolism of this case with those known to be carcinoma, experiments were carried out for two weeks.

TABLE 8.

PERIOD 1.			
Nitrogen of food.		Nitrogen of excreta.	
13.0	13.6	14.6	13.1
14.2	13.0	15.2	13.2
15.5	14.2	14.5	13.5

11.4	13.3	12.3	11.2
10.7	12.3	11.7	12.4
10.7	12.3	11.7	9.4
PERIOD 3.			
Nitrogen of food.		NaCl of excreta.	
16.8	14.8	11.7	9.5
16.8	17.6	11.7	11.9
16.9	15.6	11.7	10.9
17.0	13.6
17.1	14.6

During the first six days a fairly accurate nitrogenous equilibrium was maintained, while a slight retention of chlorid was manifested, although these results were not as accurate as the nitrogen determinations. During the next period of three days the nitrogen of the food was reduced to 10.9 gms. daily which resulted in an average loss of 1.7 gms. daily, while the chlorid was maintained at a fairly high level, .9 gm. being retained by the system. During the third period the nitrogen in the food was increased to from 16.8 to 16.9 gms. daily, resulting in a retention of nitrogen. The patient gained weight and showed marked improvement with a diet containing 16 gms. of nitrogen. During three days of this period chlorid equilibrium was maintained very well, 11.7 gms. in the food being followed by a loss of 11.1 gms. in the urine.

A source of experimental error which may be mentioned is the loss of nitrogen and chlorid by the skin, which, if taken into account, might rectify small differences between ingestion and excretion. The small amount of work which has been done along this line indicates a normal loss per day of from .1 to .2 gm. of nitrogen and from .2 to .3 gm. of sodium chlorid.

SUMMARY OF DATA.

The following table gives the average of chlorid and nitrogen of food and excreta in normal, cancer and doubtful cases.

TABLE 9.

Case.	N. of food.	N. of excreta.	NaCl of food.	NaCl of excreta.
1. Normal	a 13.0	13.4	11.4	11.9
	b 11.6	13.2	13.2	13.5
2. Carcinoma of stomach and pancreas	a 6.5	6.5	1.85	1.8
	b 5.5	6.7	1.6	.9
	c 4.3	6.7	1.9	.45
3. Carcinoma of esophagus involving stomach and liver	9.4	8.5	5.4	4.45
4. Carcinoma of kidney	4.5	6.8	2.1	.4
5. Sarcoma of skin and connective tissue	11.5	11.1	7.8	8.1
6. Epithelioma of uterus, etc.	8.1	9.0	6.0	5.7
7. Cardio-spasmus (infection)	a 12.3	17.1	5.4	5.6
	b 13.7	13.5
8. Esophageal stricture (cause undetermined)	a 14.4	14.7
	b 10.7	12.6	11.9	11.0
	c 16.9	15.2	11.7	10.8

11. A diagnosis of carcinoma of the esophagus was subsequently made.

SUMMARY OF EXPERIMENTAL FEEDING.

Case 1. A normal individual was submitted to partial proteid starvation, while the quantities of chlorid were varied. A loss of nitrogen resulted, while chlorid equilibrium was maintained.

Cases 2 and 4 were suffering from carcinoma and were cachectic. The experiments were carried out until death. There was a constant loss of nitrogen and retention of chlorid, but the loss of nitrogen was but little above the loss sustained by a normal individual in a state of starvation, indicating that this loss was not of necessity due to the toxic influence of the tumor.

Case 3. This patient had positive cancer of the stomach and liver, yet showed, instead of a loss, a retention of nitrogen and the expected retention of chlorid. One source of error was the loss of nitrogen through expectoration. Death prevented a repetition of the experiment.

Case 5. This patient showed how little effect a growing sarcoma had on nutrition, a balance of nitrogen and chlorid for twelve days being maintained.

Case 6. This patient, suffering from epithelioma of the vulva, showed a slight loss of nitrogen and retention of chlorid, the slight loss of nitrogen being possibly explained by the inability perfectly to control the patient for experimental work.

Case 7. This cardio-spasmus patient showed a loss of nitrogen during the first period, probably due to the operation and subsequent infection, and maintained a fair equilibrium of chlorid. During the second period equilibrium of nitrogen was maintained.

Case 8. This patient, suffering from stricture of the esophagus, due to unknown causes, maintained nitrogen equilibrium on 14 gms. per day, but retained nitrogen when receiving more and lost when receiving less. A slight tendency to chlorid retention existed.

In conclusion, it must be admitted that none of our patients showed an absolutely accurate balance, of body weight, loss and gain of nitrogen and chlorid, increase in weight of tumor, loss of tissue and production of edema. But when we note the loss of nitrogen and chlorid by the skin and mouth and other experimental errors a fair balance may be struck.

A most important conclusion has already been noted in the text, namely, that a healthy individual was able to assimilate enormous quantities of chlorid and strike a balance in from twenty-four to forty-eight hours, while cancer patients showed edema when chlorid consumption was increased, the kidneys being unable to excrete the excess.

The great significance of the rôle played by soluble chlorids in the process of oxidation and elimination of waste products can not be overlooked.

Work of this nature shows the presence in the system of toxic substances capable of interfering to a certain extent with nutritive processes. These toxic bodies are not proved to be specific cancer poisons, but may be sub-oxidized nitrogenous products.

Nonsectarian Medicine.—Sectarianism in medicine is founded in selfishness and commercialism. It is a stumbling block to the science and art of medicine. The goal of medical science is truth, and the application of truth to the prevention and cure of disease. To the physician all known truth should be available, all plausible theories should be his to prove. No dogma should fetter his choices, no school should select his remedies, no sect determine his methods.—*Columbus Medical Journal*.

CONGENITAL COXA VARA.

HENRY O. FEISS, M.D.
CLEVELAND, OHIO.

E. S., 3-year-old girl, a patient of Dr. O. T. Maynard's of Elyria, was referred to Dr. E. F. Cushing, who kindly referred her to me Oct. 10, 1905.

History.—The family history showed nothing of importance. The mother was well developed and healthy and had several other normal children. Pregnancy was normal. The birth ran smoothly, but at delivery Dr. Maynard noticed that the legs were in a peculiar position. The right one was flexed with the knee pointing outward in the normal way and the lower leg placed across the abdomen, but the left leg, instead of being in a position symmetrical to the right, had its thigh adducted into approximation with the right thigh. The knee was sharply flexed and the lower leg ran parallel to the lower leg of the right side, the foot being turned outward at the ankle. This position having been noted, the doctor drew the legs down and noticed an extreme flexibility at the left hip joint, suggesting congenital dislocation. No ophthalmia was noticed.

After this the child was kept under careful observation, and developed and nursed well, the hip not getting any worse, and treatment was deferred to a later period.

On walking, at about 18 months, the child limped on her left leg, the limp not being very extreme, but noticeable. There never was any sign of inflammation, no abscess, no stiffness, no night cries, no history of injury.

Examination.—The examination showed a well-developed and nourished child, very active, but limping slightly on her left leg. The examination of her shoulders, spine and other joints showed nothing. There was no glandular enlargement, no rosary, no enlarged epiphyses and no other signs of rickets. The examination of the right leg showed nothing. In the left leg the patella was situated higher than in the right.

In the left hip the trochanter was prominent and elevated, being well above Nélaton's line. Motions were not limited except to a moderate degree in abduction and external rotation. On manipulation the head of the bone could not be located out of its socket, but there seemed to be a peculiarity about the joint compared to that of the other side, as though the neck had lost its normal angle with the shaft. The left knee was somewhat knocked. There was some pronation at the ankles. Besides this there were no defects nor deformities. Measurements from the great trochanter to the knee joint showed the shafts to be about equal. Measurements of the leg were as follows: A. S. S. to I. M., right 16, left 15½; umbilicus to I. M., right 16¼, left, 17¼; circumference right thigh 10½, left, 10½; circumference right calf 7¼, left 7¼.

Thus there was no atrophy and only one-half inch shortening, apparently due to something wrong about the hip joint. A Roentgen picture was taken which explained the condition. (Fig. 1.) On this the neck of the bone is seen to be shortened and thickened and placed at a right angle to the shaft. The epiphysis is only one-fourth the size of that of the other side. The acetabulum is exactly like that on the right. The pelvis shows nothing wrong and the femoral shaft is not atrophied. The apparent thickening is probably due to the fact that the two legs presented a slightly different angle to the tube. The thigh is in a position of slight adduction.

The evidence in this case is, we believe, sufficient to prove its being congenital. The peculiar position of the thigh, that is, the extreme adduction, and the extreme flexibility noticed right after birth, point to its intra-uterine origin.

REVIEW OF LITERATURE.

Kredel¹ was the first to call attention to the possibility of the congenital occurrence of this deformity. He reported two cases. The first case, seen at three years, was a double coxa vara with other congenital deformities of the limbs, namely genu valgum and pes equinovarus. The second case was unilateral coxa vara, genu

1. Kredel: *Centralblatt f. Chir.*, 1896, No. 42.

valgum and pes equino-varus of the same leg, together with absence of the patella, severe genu valgum and pes equino-varus of the other limb. The legs in these two cases lay parallel and adjoining and directed toward the left so that they formed an angle with the trunk of 135 degrees. The left or normal hip was abducted and the right or deformed hip was adducted. He states: "When one has seen this well-nourished and active child taking this position repeatedly, then one cannot doubt the fact that both the legs had been constrained and had grown in this position in utero for a long period."

The next report on this subject is by Zehnder,² who reports a double case in which the birth was normal and in which the child walked at the age of one year, but waddled at the very start. There were no other defects or deformities described. The same year Kirmisson,³ writing on this subject, reported the case of a child nine years old with rachitic deformities. The femoral diaphyses had enormous curves convex anteriorly and exteriorly. These curves were continued into the neck of the bone, producing coxa vara. He also reports two autopsies on rachitic infants shortly after birth, in which the deformities were the same as in his first case.

The next report is by Mouchet and Aubion.⁴ They report two cases. The first case was double, with unimportant history and no rickets. Both legs had a total concave bend inward. The second case was single, also without rickets. The authors further call attention to a radiograph of a hip of a child, which they believe to have been an intrauterine fracture of the neck, founding their belief on the radiograph. This lesion resembled the first two cases and suggested such a fracture as being possible, especially as postuterine fracture could be eliminated in both.

The next report is by Joachimstahl,⁵ who believes that in two cases which he reports he had a type of coxa vara which has clinical relationship with those occurring in the earliest period of extrauterine life, but he calls attention to a less typical form of congenital coxa vara, which has a relation to congenital defect of the femur. He reports a case in which a severe coxa vara occurred on the right side, with a defect of the upper part of the shaft, and an extreme coxa vara on the left. The author calls attention to a case which Drehmann reported, and reports one which is parallel, the two cases showing similar combinations. He calls attention to the fact that besides the defect in the femur and the bend at the upper end of the stump, there occurred a decided retardation of the ossification of the upper part.

Parallel with Joachimstahl's report we find the report of Reiner⁶ on the relationship between congenital coxa vara and congenital femur defects. He believes that congenital coxa vara is a preceding stage in a deformation process leading to the defect of the femur. He says that there are three types of this condition, each of which represents a different stage in the same process. In the first type, or the first stage, we have congenital coxa vara. At the same time the shaft is shortened both in length and caliber. The other two stages are represented by greater defects in the femur, even by total absence, but he emphasizes the fact that each one of the three types is a fixed stage of one and the same deformation process.

The process is referred to as a "modellirendes trauma" beginning in the amnion. What influences the forma-

tion of the deformity is the peculiar course of development through which the femoral shaft passes in its earliest period of embryonic life. At about the tenth week the proximal end of the femur is subject to a transformation process in which the thigh, which is normally abducted in relation to the pelvis, instead of this is now adducted and turned inward, while at the same time the formation of the angle of the neck of the shaft takes place.

Recently Clark⁷ reported a case of congenital coxa vara with associated deformities in a girl two years old, in which the Roentgen picture showed on the left side a typical coxa vara. The other deformities were a bend at the left knee joint of 45 degrees, with absence of the patella and the quadriceps. The foot was in a position of talipes equino-varus. On the right side there was genu recurvatum and talipes calcaneo-valgus. Besides this the radiograph showed the sacrum deflected to the deformed left side and that the upper side of the os innominatum was flattened.

Before concluding this review it is necessary to refer to the conditions described by Drehmann⁸ with reference to joint inflammation in sucklings and their etiologic relation to later deformities. He says that in the earliest age we may have a typical joint inflammation, beginning with local signs, followed by healing and later by deformity. He points out the relation of this condition to an infection such as the gonococcus, but not necessarily this organism. He says that a slight trauma during delivery would predispose toward auto-infection. Among these cases he says there are some so-called congenital dislocations and rarely a coxa vara. He reports two of the latter, one of them typical. The point is that such deformity, according to the author, can not be distinguished from the so-called congenital ones.

DISCUSSION OF CASE.

This review, we believe, covers all the important works on congenital coxa vara up to date. The relation of my case to those reported is of some interest. With regard to Drehmann's deformities at the suckling age, I do not believe that mine comes under that category, for there was no history of ophthalmia and no local signs pointing to inflammation.

The rachitic deformities in a few of the cases have nothing to do with mine, as there were no signs of rickets. The question of associated deformities or defects which occurred in so many is an interesting one, because the only other deformity in my case was that of a knock-knee. According to Reiner's belief that coxa vara is one stage in a process leading to femur defects, this case would readily find its place in his classification were it not for his observation that the shaft is shortened both in length and caliber even in the first stage. My case does not answer to this description.

As to the theoretical origin of the deformity *in utero*, we believe that the mechanical conditions are sufficient to explain that. Reiner's theory that at the end of the tenth week the angle of the neck of the shaft is determined by intrauterine conditions seems reasonable as an explanation which is founded on the fact that the femur, instead of being abducted, is adducted. In this connection it seems worth while to place a fetus in the position which my case seemed to have had at birth.⁹

6. Reiner: Zeitschrift f. Orth. Chir. vol. xii, Nos. 1 and 2.

Taking an eight months' fetus, hardened in formalin, we placed the right leg in its normal position as it occurred at birth, that is, flexed and abducted and then forcibly adducted the left leg on the belly so as to adjoin the other one. Tying the thighs in this position, we took a Roentgen picture of the fetus (Fig. 2.) The pic-

Figure 1.

ture shows a different relationship of the proximal ends of the femur to the acetabulum on the two sides. On the right, or normal side, the proximal end lies in a horizontal plane with the lower extremity of the pelvis. On the left, or adducted side, we find the end of the shaft well above the acetabulum in height. Besides this

an exactly similar deviation is shown in Clark's radiograph. This means that we have probably demonstrated correctly the mechanical nature of the intrauterine strain.

If my case took the position of this fetus in the uterus we have a right to assume that the relationship must have become fixed and maintained for a long period, but without interfering with the freedom of motion of the joint. Then, after birth, the joints' ends must still further have maintained their relation to the pelvis, the left end remaining higher than the right, even after both legs have been brought downward into their extrauterine positions. This hypothesis is favored by the fact that ossification in the neck takes place from the shaft and travels upward toward the head which ossifies in the acetabulum from a separate center during the first year.

An interesting feature in my case is a diminution in size of the epiphysis of the head. On Clark's radiograph an epiphysis is not recognizable. The explanation of this is either the faulty static conditions of weight bearing, or retarded growth, due to a lesion of the neck. The shortening of the neck, together with thickening, suggests an intrauterine fracture, but we are not able to conceive a fracture in the true sense where the bone has not yet been formed.

CONCLUSIONS.

Congenital coxa vara is usually associated with defects or deformities of other parts, commonly with the defect of the femur and with deformities of the lower limbs. It may be intrauterine in its strictest sense, it may be the result of an intrauterine infection, or it may be combined with congenital rachitic deformities. At least some of the strictly intrauterine cases are associated with peculiar positions of the thighs in utero, that is, adduction of the thigh in question. This peculiar position of the joint might explain a fixed deformity in the later developing hip joint, if we may assume that the proximal end retains its relative position to the acetabulum after birth.

MORPHOLOGIC AND HISTOGENETIC CHARACTERISTICS OF ENDOTHELIAL TUMORS.

F. ROBERT ZEIT, M.D.

Professor of Pathology, Northwestern University Medical School and Postgraduate Medical School.
CHICAGO.

A careful examination of the literature, not only of the past, but also the present, has convinced me that many of the tumors reported as carcinomata and sarcomata as well as tumors such as Krompecher's "carcinoma endotheliale" or Hansemann's "adenoma endotheliale," are in reality pure endothelial tumors. The latter author even speaks of a "carcinoma sarcomatodes endotheliale," thus combining three distinct groups of tumors in one. Krompecher speaks of a "carcinoma endotheliale sarcomatodes," and calls an endothelioma a carcinoma with undifferentiated epithelium, naming it a "carcinoma endotheliale." It can only be an endothelioma which is capable of producing polymorphous structures leading to such complications of names.

The variability in the arrangement of endothelial cells and the ability of these cells to undergo metamorphosis, simulating the epithelial type at one place and the connective tissue type at another, has given rise to great confusion in the diagnosis of tumors. Morphologically, an endothelioma may resemble typical (adenoma)

Figure 2.

the pelvis is tilted upward on the left and the sacrum deviated toward the same side. This deviation of the sacrum toward the deformed hip is an important point, for

or atypical (carcinoma) organoid structures or typical (fibroma) or atypical (sarcoma) histoid growths.

It is extremely confusing for the student who has learned to diagnose common atypical histoid growths, as sarcomata and atypical organoid tumors as carcinomata or endotheliomata, to read of the diagnosis of an atypical organoid tumor by Billroth as alveolar sarcoma; by Rindfleisch as sarcoma endotheliale; by Waldeyer and Kolacek as angiosarcoma; by Fischer and Cramer as endothelial sarcoma, because atypical organoid tumors

their morphology (atypical organoid tumors are cancers). But according to their histogenesis, they are not cancers at all. The greatest confusion has thus been brought about in the nomenclature of a class of tumors, which could neither from a histogenetic point of view nor from a purely morphologic one be classified either with the epithelial or with the connective tissue tumors. Endothelial tumors simulate morphologically the

Fig. 2.—Lymphangioendothelioma intravasculare of uterus. Alveolar structure, Van Gieson stain

Fig. 4.—Lymphangioendothelioma intravasculare of uterus. Island of endothelial cells showing lumina filled with mucoid material. The cells around the lumina are somewhat cylindrical, hinting tubular glands.

exclude for him the connective tissue growths. Here the tumors are diagnosed by their histogenesis.

All these organoid sarcomata are really endotheliomata, and thus by their histogenesis are very closely related to the atypical connective tissue tumors, whereas by their morphology alone they resemble the organoid or epithelial tumors, and are called by Schulz endothelial cancer, by Neumann connective tissue cancer and by Cramer cancer. They have been diagnosed according to

atypical epithelial tumors, and histogenetically, the atypical connective tissue growths; but they only simulate them and can not be included with either type. Whenever this was done it either upset the whole system of practical diagnosis, or it violated the only scientific classification of tumors, that is, a histogenetic one.

Unfortunately, we can not always see the earliest steps in the formation and propagation of a tumor in

the living tissue, but must depend on interpreting these processes from histologic examinations. In the endothelial tumors we compare the parenchyma with normal endothelium just as we divide epithelial tumors histogenetically by comparison with normal squamous and cylindrical epithelium into two classes. Here also our diagnosis lacks exactness at times, because we are unable to decide whether we are dealing with squamous

and lymph vessels may form histogenetically heman-gioendothelioma and lymphangioendothelioma, respectively.

Embryologically, these tumors should belong to the connective tissue group, but endothelial cells resemble in many respects epithelial cells, and stand about midway between epithelial and connective tissue cells, which

Fig. 5. —Lymphangioendothelioma intravascular of uterus. Endothelial cell nest with lumina containing a delicate fibrillar network, which stains red with polychrome methylene blue and is coagulated by acetic acid.

Fig. 7. —Lymphangioendothelioma intravascular of submaxillary gland.

accounts for the fact that endotheliomata have been called at one time epithelial growths (carcinomata), and at another time connective tissue growths (sarcomata). Histogenetically, they belong to the connective tissue tumors, because these flat endothelial cells may become

Fig. 6. —Lymphangioendothelioma intravascular uteri. Structure similar to carcinoma. Large vessel with proliferated intima, containing many lumina. The vessel lumen is still visible.

Fig. 8. —Hemangioendothelioma perivascular of muscle sheath (arm).

or with cylindrical epithelium histogenetically. If we follow the general rule of attaching the end syllable "oma" to the name of the normal tissue which is the nearest related to the tumor tissue, morphologically as well as biologically, a growth which originates thus histogenetically from endothelium should be called endothelioma. Thus the endothelium of blood

cylindrical, form spindle cells and appear as fibroblastic elements.

CLINICAL SIGNIFICANCE OF ENDOTHELIOMA DIAGNOSIS.

A correct diagnosis of endothelioma is of the greatest practical value to both surgeon and patient, because endothelial tumors differ greatly clinically from other malignant tumors in that they are of slower growth

and do not produce metastases until late, when the tumor has reached considerable size. The neighboring lymph nodes are not early affected, as is common in carcinoma. The prognosis after thorough removal is much better and a cure much more probable than in carcinoma or sarcoma. Endotheliomata, however, are exceptionally prone to recur at the seat of operation, much more so and much earlier than carcinomata.

NECESSITY FOR A SYSTEM OF DIAGNOSIS.

In view of these clinical facts, a system of accurate diagnosis of endothelial tumors becomes of the greatest importance. Endothelial tumors are very commonly mistaken for carcinomata morphologically, because these tumors have an atypical organoid structure resembling epithelial neoplasms, whereas, histogenetically, they are of mesoblastic origin, and endothelial tumors are thus included under atypical connective tissue growths, although their cells are morphologically very different from connective tissue cells.

The struggle between the purely morphologic and the purely histogenetic classification in the different text-books, and the fact that these tumors differ very much in their clinical behavior from carcinomata and sarcomata, demonstrate the necessity of recognizing endothelial tumors as a class by themselves.

I can not at all agree with Hansenmann and Ziegler, who propose to solve the problem by including endothelial tumors with epithelial neoplasms because they correspond in their structure and clinical behavior to the epithelial tumors of the ectoderm and entoderm. It is just this difference in clinical behavior, the slow growth, the late metastases and the better prognosis after thorough removal of endotheliomata, which distinguishes these growths from the carcinomata and makes a correct diagnosis so essential.

A practical system of diagnosis would seem to lie in entirely detaching endothelial tumors from the other tumor groups and in the establishment of a separate class of endothelial tumors, without disturbing the usual and useful system of histologic and histogenetic classification in this way:

1. Epithelial tumors (organoid); typical (benign), and atypical (malignant).
2. Endothelial tumors (organoid).
3. Connective tissue tumors (histoid); typical (benign) and atypical (malignant).
4. Teratoid tumors.

According to whether the endothelial proliferation originates from lymph vessels and lymph tumors or from blood vessels, and whether the inner endothelial lining of the vessels proliferates or the outer, the endothelial tumors may be further classified:

1. Lymphangioendothelioma intravasculare.
2. Hemangioendothelioma perivasculare.
3. Hemangioendothelioma intravasculare.

When marked hyaline degeneration is present in any of these morphologically distinct types, we may add to the above names "cylindromatosum." Instead of speaking of a perithelioma, we use the term perivasculare. I will discuss the reasons for the various changes later.

For a really scientific foundation, such a system should have not only a morphologic basis, but a biologic and histogenic one as well. Morphologically, endothelial tumors appear like carcinomata; histogenetically, they should be sarcomata. To justify the consideration of endothelial tumors as a separate class and to determine the various types of endothelial tumors which, morphologically, may simulate carcinomas, adenomas and sarcomas, it will be necessary to prove:

1. That endothelial cells can be considered as a special type of cells, biologically different from epithelial and connective tissue cells.

2. That certain characteristic morphologic distinctions exist between endothelial tumors and those that resemble morphologically (carcinoma) and histogenetically (sarcoma).

3. That such morphologically characteristic endothelial tumors can be traced histogenetically to pre-existing endothelium.

ENDOTHELIAL CELLS BIOLOGICALLY SPECIAL CELLS.

Since His invented the word endothelium for the flat cells which constitute the inner lining of the blood and lymph vessels and of serous cavities, and differentiated these cells from epithelial cells, pathologists have spoken of tumors originating from these cells as endothelioma until Stoehr, Ranvier and other histologists began to classify them as true epithelial cells, because morphologically they resembled squamous epithelial cells, thus neglecting their apparent but embryologically contested mesoblastic origin entirely. The result was that some pathologists considered these tumors as epithelial neoplasms (carcinomata). The more observing noticed that these tumors differed morphologically from squamous cell carcinomata and spoke of endothelial cancers. Embryologically, it is generally conceded that endothelial cells of blood and lymph vessels are developed from the mesoderm, although some embryologists contend that they are formed by the entoderm. The mesoderm also is said by one school of embryologists to originate from the ectoderm and by another school from the entoderm. It is plain, therefore, that the pathologist can not classify endothelial tumors by embryologic data as a basis, either with the epithelial or the connective tissue tumors.

Borst² defines the endothelial cell as a morphologically and functionally well-characterized cell form, a modified connective tissue cell, specially differentiated at the shores of plasmatic streams, and includes under endothelial cells all cells which form one layer of flat cells, lining serous cavities, meningeal lymph spaces, inside and outside layers of blood and lymph vessels and the lymph spaces of connective tissue.

From a biologic point of view, endothelial cells can be readily differentiated from other connective tissue cells by their ability to secrete mucin, hyaline and amyloid material, thus imitating the secretory functions of epithelial cells (Heidenhain³).

On the other hand, endothelial cells are capable of producing connective tissues in the inflammations of serous cavities, blood and lymph vessels, producing granulation tissue, epithelioid cells, giant cells, as well as intercellular cement substance. They may again take on their embryologic columnar cell form and produce adenoma-like tubules lined with one layer of cylindrical cells like epithelium.

These are the reasons for the polymorphous nature of endothelial tumors which may simulate the structure of a carcinoma, an adenoma or various types of sarcomata and which have given rise to the confused diagnostic nomenclature in the literature of tumors. Borst has collected a number of such diagnoses from the literature, which, from the descriptions of the authors, are plainly endothelial tumors, as follows:

Robin, epithelioma of serous membranes; Schulz, endothelial cancer; Rindfleisch, sarcoma endotheliale; Fischer and Cramer, endothelial sarcoma; Neumann,

2. Lehre von den Geschwülsten, 1902, pp. 276 and 292.
3. Pflüger's Arch., vol. xlix, p. 269.

connective tissue cancer; Ewetzky, sarcoma plexiforme; Billroth, alveolar sarcoma; Waldeyer, Kolaczek and Hippel, angiosarcoma; Arndt and Maier, carcinoma cerebri; Schottelius, lymphangitis carcinomatosa; Billroth, cylindroma; Burkhardt, perithelioma; Böhm, sarco-carcinoma; Sattler, carcinoma sarcomatosum; Hansemann, carcinoma sarcomatodes endotheliale; Nauwerek, hyperplastic capillary angioma; Hansemann, adenoma endotheliale; Hansemann, carcinoma endotheliale.

GENERAL MORPHOLOGIC CHARACTERISTICS OF ENDOTHELIAL TUMORS.

Endotheliomas have certain general characteristics which distinguish them from other atypical organoid tumors (carcinomas):

1. The tumor cells in endothelioma are intimately connected with the stroma, and can not be brushed out of the stroma, as is the case in carcinoma in which the epithelial cells may also retract from the stroma and show spaces.

2. Endothelial cells produce intercellular cement substance and are closely packed together, whereas the epithelial cells in carcinoma have no intercellular substance and form no compact layers.

FIG. 14. Recurrent hemangio-endothelioma perivascular on arm, 4 months' growth.

3. In endothelioma delicate fibrillar processes extend from the walls of the alveoli into the proliferated endothelial cell masses. These are absent in carcinoma.

4. In endothelioma the cell masses consist of a dense mosaic of many layers of cells with small, sharply outlined nuclei, surrounded with a broad envelope of clear, glassy perinuclear protoplasm. Carcinoma cells have large vesicular nuclei, with a moderate amount of perinuclear protoplasm, more or less granular.

5. In endothelial tumors the cells are arranged in the form of cellular cords and cylinders (round masses in carcinoma), and may separate out hyaline material (cylindroma) or form lumina-like areas (sieve-like) in the cellular cords, due to secretory processes of endothelial cells.

6. To distinguish the endothelial tumors from sarcoma it is to be remembered that the former have an organoid, the latter a histoid, structure. According to

this definition every large-cell sarcoma with a well-developed stroma, which was formerly called alveolar sarcoma, would be called an endothelioma.

SPECIAL MORPHOLOGIC CHARACTERISTICS OF THE VARIOUS TYPES OF ENDOTHELIAL TUMORS.

From a large amount of material collected during the past eight years I have chosen six cases which will illustrate the various points made in this paper and the reasons for the adoption of a nomenclature, which is justified in view of its practical nature as well as its well-formed morphologic and histogenetic basis.

Lymphangi endothelioma Intravasculare.—Such tumors occur most frequently in the salivary glands, skin, meninges, testicles, ovaries, bones, serous membranes, stomach and mammary glands. This tumor has an organoid structure, consisting of a fibrillar matrix and connective tissue stroma, arranged in rows (Fig. 1) or forming an alveolar structure (Fig. 2), and more or less solid cords or columns of endothelial cells. These solid cellular columns may be seen, at the circumference of the tumor, to be continuous with branching net-like narrow cellular strips which invade the neighboring connective tissue and produce the appearance of newly forming lymph vessels, and are in reality the youngest forms of the tumor cells, infiltrating and invading the surrounding tissue. The larger, solid and older cellular columns frequently have a sieve-like appearance, due to the formation of so-called lumina (Fig. 3). These lumina, although resembling the lumen of capillary lymph vessels within the endothelial cell mass, are produced by a secretory process of endothelial cells. This secretion may collect in larger or smaller amount. It gives the same reactions as mucin (Fig. 4). In my specimens the so-called lumina contained a fine fibrillar network which stains blue with alum hematoxylin and pink with polychrome methylene blue (Fig. 5). Acetic acid coagulated it. The endothelial cells around these so-called lumina are pressed on and take on cylindrical shapes, so that pictures like tubular glands may be produced (Fig. 4).

The endothelial lining of a lymph vessel may proliferate so that its intima consists of many densely packed layers of polygonal cells with small distinct nuclei (Fig. 1), abundant glassy perinuclear protoplasm and distinct intercellular cement substance producing a mosaic picture. The lumen of the lymph vessel may be obliterated (Fig. 2). If a lumen still remains in such a vessel and it happens to be surrounded with a good deal of fibrous tissue stroma the structure may resemble a glandular carcinoma very much (Fig. 6). The lumen of the lymph vessels then resembles the lumen of a gland, and the proliferated endothelial cells of the intima may then be taken for the atypical proliferation of epithelial cells which line the gland in many layers. Here the lumina, the small nuclei, the rich and glassy perinuclear protoplasm of the cellular cords help to differentiate this tumor as an endothelioma, particularly if other solid cellular cords also have lumina and if the younger circumferential areas of the growth show the invading, branching, net-like, narrow strips of proliferating endothelial cells in connection with the older, more solid, cellular columns.

The stroma frequently forms an alveolar arrangement so that such a tumor has been called alveolar sarcoma (Fig. 2). Ribbert goes so far as to include every large round-cell sarcoma with well-developed alveolar stroma under endothelioma. Borsl warns against calling every round cell sarcoma which happens to have an insignifi-

cant fibrillar reticular framework, an endothelioma. He demands the proof of the endothelial origin of the tumor and then names it endothelioma alveolare. On the other hand, the fibrous tissue stroma may be so prominent in some of the endothelial tumors as to simulate scirrhus carcinoma or even fibroma. The so-called endothelial cancers of serous membranes, as well as the diffuse colloid carcinoma or carcinoma gelatinosum of the peritoneum, are also to be included under lymphangioendothelioma.

In addition to the points here made for a diagnosis of endothelioma, it is necessary that the tumor possess the general differential characteristics, already mentioned, which distinguish it from certain tumors of epithelial or connective tissue type. The special morphologic characteristics of a lymphangioendothelioma are well illustrated by the three following cases:

LYMPHANGIOENDOTHELIOMA INTRAVASCULARE OF UTERUS.

The first case is one of lymphangioendothelioma of the uterus which occurred in the private practice of Dr. Emil Ries, to whom I am indebted for the material.

This case is of general interest because very few endothelial tumors of the uterus have been reported, and of those found in the literature none presents an endothelial neoplasm so extensive as that shown in this case. It presents such characteristic microscopic features that a diagnosis was made from a cervix curettement before hysterectomy.

According to the literature, a curettement diagnosis of endothelioma of the cervix has been made only once by Gebhard, and in his case there were such extensive tumor masses in the parametrium that no operation was attempted.

Although the microscopic and diagnostic features described in the few cases found in the literature closely correspond with those I found in this case, not one of them shows the extensive, diffuse endothelial infiltration and proliferation present in this uterus, converting the whole organ, body and cervix into a solid neoplasm of the shape of a nearly normal uterus, the only portion escaping being a small area of the fundus.

The patient, aged 68, had four children and presented the clinical symptoms of uterine carcinoma.

Treatment.—A vaginal hysterectomy was done and, to our great surprise, a fairly normalized uterus was found of very hard and fibroid-like consistency, 3 inches (75 mm.) in length and $1\frac{1}{2}$ inches (37 mm.) in breadth.

Result of Operation.—The patient died $11\frac{1}{2}$ months after the hysterectomy with multiple metastatic tumors of both pleurae, lungs, bronchial glands, diaphragm, liver, both kidneys, right adrenal, pelvic lymph nodes, rectum and left sacral plexus, all of which showed the same cell cords, with lumina and general structure as described in the uterine neoplasm.

Description of Growth.—The uterus was sectioned longitudinally. The uterine cavity was obliterated, except a small narrow slit extending $\frac{3}{4}$ of an inch (25 mm.) down from the fundus and just admitting a probe. This probe could also be introduced into the cervical canal for $\frac{3}{4}$ of an inch (25 mm.). The atresia extended from the middle of the cervical canal to the middle of the corpus. The anterior and posterior lips of the portio were enlarged and hard. The whole cervix and all the body of the uterus, except the fundus, consisted of a hard, tumor-like mass, retaining the shape and size of a normal uterus, but of a white, rather fibrous or scirrhus appearance. The fundus alone retained the usual color of uterine musculature for an area of $1\frac{1}{4}$ by $\frac{3}{4}$ inches (32 mm. by 25 mm.).

The cut surface of the growth had a smooth, white appearance, with fine irregular and round mosaic-like fields. The whole uterus, except the fundus, appeared to be one large

tumor nodule. The mucosa was smooth, atrophic and glistening.

No metastatic tumors were found by Dr. Ries at the time of operation.

Microscopic Examination.—Sections were made from all parts of the tumor and stained by the common and by special staining methods.

The whole uterus, except its fundus, showed a fibrillar ground substance, with solid cellular cords, cut in longitudinal and transverse sections (Fig. 2). These cellular cords reminded one, in their distribution and character, of lymph spaces. Lymph vessels and lymph spaces traversing this fibrillar connective tissue were lined with proliferating epithelioid cell masses. These cords of cells appeared like cellular cylinders of large diameter (lymph vessel endothelioma) or as delicate cell strips of two layers of flat cells branching here and there (lymph space endothelioma). Both of these forms were combined in some of the fields. The larger endothelial cell masses had numerous so-called lumina containing mucoid material (Figs. 3, 4 and 6).

Other portions of the tumor looked like scirrhus carcinoma, and the dictum of Hansemann, that most scirrhus carcinomata of the uterus, stomach and esophagus are endotheliomata, will find by these specimens a substantial support. There were large areas with a stroma of dense fibrous tissue and alveolar arrangement of endothelial cells, as seen in glandular carcinomas (Fig. 6). This organoid, carcinoma-like type is found more often in endothelioma of lymph vessels than of lymph spaces. The so-called lumina contained a delicate fibrillar network (Fig. 5) or a homogeneous material (Fig. 4) which stained pale-blue with hematoxylin. With polychrome methylene blue the tissue stained blue, whereas the delicate network in the lumina stained red, that is, like mucin. Acetic acid also coagulated it.

Some of the alveolar cell nests could be seen to be continuous with delicate cellular cords and a network of lymph spaces with proliferating cells. With the Van Gieson stain the stroma of the tumor was seen to consist entirely of a fibrillar connective tissue reticulum, all involuntary muscle fibers having practically disappeared (Fig. 2). The mucosa, lining the cavity of the uterine body, showed some interstitial hyperplasia, cystic and atrophic glands and a few small endothelioma metastases with characteristic lumina between the cystic glands.

LYMPHANGIOENDOTHELIOMA INTRAVASCULARE OF THE KNEE JOINT.

This case occurred in the practice of Dr. A. H. Ferguson.

Patient.—A night watchman, aged 36, noticed, a few months after a fall on his knee, a small growth at the outer side of the patella. When removed by Dr. Ferguson it appeared as a circumscribed, encapsulated, oval and flat fibrous growth attached to the synovial membrane.

Microscopic Examination.—Microscopically the tumor consisted of a fibrillar connective tissue stroma which formed a network of long, wavy strands when cut longitudinally and circles when cut transversely, inclosing densely packed cellular cords of round cells with small nuclei and abundant, transparent, perinuclear protoplasm, with distinct intercellular cement substance (Fig. 1). Some of these cellular columns had a large or narrow lumen which contained a small amount of finely granular or mucin-like material; in others the lumen was obliterated and a solid cord of proliferated endothelial cells of the intima was formed, surrounded by strands of fibrous connective tissue. Only a few lumina were seen in the solid endothelial cell-cylinders.

Subsequent History.—The diagnosis was lymphangioendothelioma, but was doubted because for $2\frac{1}{2}$ years the patient had no recurrence of the growth. A nodular growth then appeared in the popliteal space, and after this had attained the size of a hen's egg Dr. Ferguson operated again, but was unable to remove the entire growth because the internal popliteal nerve and the popliteal artery and vein appeared to be included in the lobulated tumor mass, which was found partially circumscribed, partially infiltrating the tissues in the popliteal space. Microscopic examination revealed identically the same structure as that of the extrapatellar tumor removed $2\frac{1}{2}$ years previously.

Amputation of the limb was not consented to by the patient, and he again attended to his regular duties as night watchman for eight months, when the growth in the popliteal space gradually enlarged and, for the first time, three and one-half years after the appearance of the primary tumor, the inguinal glands showed metastatic enlargements, which made the prognosis bad, although the patient now insisted on amputation and was operated on. He died about eight months later with multiple metastases in many organs.

Remarks.—I am firmly convinced that if the man had consented to an amputation when Dr. Ferguson and myself advised it he would have lived. This case illustrates well the slow growth of endothelial tumors and the late metastases as compared with carcinomata and sarcomata, and that the early recognition of an endothelioma by microscopic examination should be an indication for thorough operative removal, with a very favorable prognosis.

LYMPHANGIOENDOTHELIOMA INTRAVASCULARE OF SUB-MAXILLARY GLAND.

To contrast the two lymph-vessel endotheliomata just described microscopically with a so-called lymph-space endothelioma (although the two are frequently combined in one tumor, in which case the lymph-space growth is probably nothing more than a secondary invasion by atypical endothelial cells), I will describe briefly a third case of a pure lymph-space endothelioma of the sub-maxillary gland occurring in a woman, 69 years old, who was recently operated on by Dr. Allport (Fig. 7).

A rich stroma of fibrous tissue contained in narrow slits rows of small endothelial cells of somewhat columnar shape in one or more layers. Those lined with but one layer of cells looked like tubular glands, as long as a lymph-space lumen was still visible. When the proliferation of these morphologically characteristic endothelial cells became more pronounced, distending the lymph spaces and producing a small island of densely packed cells, characteristic lumina appeared.

The same structures also were found in the adventitia of the larger blood vessels (perivascular lymph spaces) of this growth.

HEMANGIOENDOTHELIOMA PERIVASCULARE (PERITHELIOMA).

The common tendency nowadays is to call the former angiosarcoma a perithelioma, in the attempt to indicate more accurately the histogenesis of the tumor. To what confusion this has led is best illustrated by a study of so-called peritheliomas as reported in recent literature in the light of our present anatomic or histologic knowledge of perithelium.

Such perithelial tumors have been reported from organs and tissues whose blood vessels are known to have no perithelial membranes at all, that is, from non-perithelial organs. Even in so-called perithelial organs, the capillaries never are covered with a perithelial membrane, although some authors speak of perithelial tumors as arising from blood capillaries. Von Ebner-Koellicker⁶ state that the outer surface of endothelial cells of blood capillaries is in direct contact with the ground substance of the surrounding tissue. It is just as wrong to speak of a perithelioma as arising from a lymph vessel because perithelial membranes cover the outer surface of the adventitia of blood vessels only in a one cell layered mosaic of flat endothelium-like cells. They have only been found with blood vessels of certain organs called perithelial organs.

A perithelioma can not, therefore, be spoken of as arising from lymph vessels nor from blood capillaries. This, then, confines the term, perithelioma, to certain in-

mors of the blood vessels of perithelial organs only. Yet so-called perithelial tumors or angiosarcomata do occur in non-perithelial organs which are morphologically similar, but only similar, to the true peritheliomata. From a histogenetic point of view it is desirable that the term perithelioma be reserved for a class of tumors arising from perithelium only. The term perithelium was applied by Eberth⁷ to an endothelium-like membrane of flat polygonal cells which lines the outer surface of the adventitia of the blood vessels of the brain and cord. The perithelial membrane must be differentiated from the perivascular lymph spaces of His,⁸ which he found surrounding the adventitia of arteries, veins and capillaries of the central nervous system (which has no lymph vessels). The perithelium is the outer lining of the adventitia of blood vessels, outside of which is the perivascular lymph space (Fig. 9).

Drissen⁹ described a bone tumor as growing from the perithelium of blood capillaries and then named it endothelioma. This explains better than anything else the confusion which exists in the literature on perithelioma. Drissen first claims that the tumor started from the perithelium, although no perithelium has been found in the vessels of bone. He claims it started from perithelium, but names the tumor an endothelioma, because he appears to consider perithelial cells as the outer endothelial layer of a perivascular lymph space. Bormann,¹⁰ in a very careful review on vascular tumors, remarks that Drissen's tumor was not a perithelioma because bone vessels have no perithelium, and it could not have been a perithelioma growing from capillaries, because capillaries never have perithelium. In regard to the latter point, it might be well to remember that the more delicate structure of capillaries in various vascular regions is not yet sufficiently understood, and that for many blood capillaries it has been proven that they are surrounded with a cellular sheath, which Auerbach and Eberth speak of as vascular perithelium and others as capillary adventitia. Sheaths of peculiar cells are found around the capillaries of the carotid gland,¹¹ the coecygeal gland,¹² and the testicle.¹³ The coecygeal gland, discovered by Luschka¹⁰ and studied minutely by Krause,¹¹ Arnold¹² and Scrofoli,¹³ has capillaries and small veins which have an adventitia of polygonal small cells.

Volkman¹⁴ wants to call these cells capillary adventitia cells and not real perithelial cells. Borst calls them perivascular cells or adventitia cells of capillaries, and says that their pathologic proliferation causes cylindrical cell mantles around capillaries like those of perithelial cells. Bormann says that capillaries never have a perithelial membrane. Perithelial cells have also been described in the adrenals, pineal gland, mammary glands and salivary glands, and many authors consider them closely related to endothelial cells. It is necessary to emphasize the fact that the perivascular lymph vessels, which are found in many organs, also have nothing to do with perithelial membranes, so that the inner layer of the perivascular lymph vessel must not be mistaken for perithelium (Fig. 9).

In order, then, to arrive at a histogenetic classification of these tumors we would have to be able to distin-

guish whether the proliferation of cells had their origin in the true perithelium of blood vessels which lines the outer surface of the adventitia in perithelial organs (perithelioma); in the inner or both endothelial layers of a perivascular lymph space; or, in the adventitia cells or perivascular cells of blood capillaries.

Pick and Rosthorn call all these endothelium-like layers perithelium and their proliferation a perithelioma. Borst also wants to use the name perithelioma for all these tumors, with the understanding that it is a kind of offspring of endothelioma. In case one is able to prove that the growth originated from the endothelium of the perivascular lymph spaces, it should be called endothelioma perivascular (Borrmann's pericndothelioma).

Borrmann thinks he can distinguish morphologically between the two types as follows: Perithelioma, when the vessels are surrounded by many layers of cells, which are arranged radially and vertically to the wall of the vessel; pericndothelioma when the vessels are surrounded by many layers of cells which are arranged concentrically around the wall of the vessel.

From a careful study of my perithelial or perivascular tumors, I am unable to verify Borrmann's morphologic distinctions, and in view of the existing uncertainties and controversy as to the nature of perithelium, endothelium of the perivascular lymph spaces and capillary adventitia cells, I prefer to use the name hemangioendothelioma perivascular, on account of the great histogenetic and morphologic similarity of perithelium, endothelium of perivascular lymph spaces and capillary adventitia. The three following cases illustrate such tumors:

HEMANGIOENDOTHELIOMA PERIVASCULARE OF LEFT ARM.

The patient, a married Polish laborer, aged 38, came to Provident Hospital under the care of Dr. J. C. Hepburn, to whose kindness I owe the history of the case.

Family History.—The patient's father is living, aged 80; his mother is dead, cause unknown; two brothers are living and well; one sister is living, one died at the age of 8 years. The patient has never been ill, except that when 7 years old he had whooping cough.

Present Illness.—The patient was first seen Dec. 1, 1903. He had excruciating pain in the left deltoid region for six weeks. He had been unable to sleep and was losing in weight. He had a small growth for 15 years over deltoid without discomfort until six weeks before applying for treatment, when the tumor began to grow rapidly and became daily more painful. He had lifted and carried heavy pieces of lumber.

Examination.—Physical examination revealed an oval tumor six inches long in the left deltoid region just below the acromion process; the surrounding tissue was inflamed. The tumor was just below the skin, which was freely movable over the growth, the latter being attached below. The tumor was hard and fibrous.

Operation.—Dec. 4, 1903. An encapsulated tumor was found attached to the intermuscular septum between the deltoid and triceps muscles; the periosteum was not involved. The wound healed by first intention, and the patient left the hospital in seven days and returned to work.

Description of Tumor.—The tumor measured 13x12x8 cm. It was oval, with globular bosses, and was distinctly encapsulated except at two places. One portion of the growth was of stony hardness, 6x6½ cm. There were several cysts, one 2½ cm. in diameter containing a clear yellow fluid. The cut surface was shining white, lustrous in the center and finely granular and friable at periphery.

Microscopic Examination.—The tumor consisted of a tangled mass of blood vessels, whose walls were surrounded by a mantle of densely packed cells, round and spindle-shaped, and arranged in circular layers around and close up to the distinctly visible intima, the lumen of which was filled with red blood corpuscles. These cellular tubes were either confluent or sepa-

rated by myxomatous tissue (Fig. 8). The patient was advised to have a complete excision of the upper extremity at once, but he did not consent and continued at work.

Subsequent History.—The man returned, four months later, emaciated, unable to sleep, no appetite, temperature 102, pulse 120. He had had no pain for two months after the operation and was able to use his arm well. Then a bean-sized, painful growth appeared at the site of the primary tumor and grew rapidly during the last two months to the tremendous size as shown in Figure 11. The tumor involved the whole external and posterior aspect of the upper three-fourths of the arm. It showed large nodular masses, with necrotic areas in the center of the two lower lobes. The axillary glands were enlarged. The growth was diffuse, the whole mass fixed and the skin adherent.

Second Operation.—April 29, 1904, the whole arm, outer two-thirds of the clavicle and the scapula were removed and the axillary glands carefully dissected out. Most of the wound closed by first intention and by the thirteenth day after the operation the man was walking about.

Result.—This extensive growth microscopically was the same as the first small tumor. On June 2, 1904, Dr. Hepburn showed the patient at the south side branch of the Chicago Medical Society. As far as known there has been no return of the growth.

HEMANGIOENDOTHELIOMA PERIVASCULARE OF MAMMARY GLAND.

If we now compare with this tumor, which grew from a non-perithelial tissue (muscle sheath of the arm) a hemangioendothelioma perivascular of the mammary gland, which is a perithelial organ, we are at once struck by the histologic similarity of the blood vessels, cell mantles and myxomatous tissues between the cellular tubes (Fig. 10), except that the cell mantles consist here principally of distinct round cells, whereas in the former case many spindle-shaped cells are intermingled with round cells. In both tumors the cells (Fig. 11) are arranged in a circular manner around the distinct endothelial ring forming the intima. According to Borrmann's differentiation, a true perithelioma should have a mantle of cells which are radially arranged. When the cell mantle consists of cells arranged in circular layers (parallel to vessel wall instead of vertically) he wants to call it a pericndothelioma. If both these tumors are false peritheliomata, it will be interesting to add here another perithelioma, which goes to show that this morphologic distinction can not always be relied on.

This case occurred in the practice of Dr. Weller Van Hook, to whom I am indebted for the material.

History.—A woman, aged 35, had a slowly growing tumor of a lymph node of the neck for three years, which a former operator removed as a tuberculous hyperplastic lymph node. A new growth rapidly appeared in the same locality, which he again removed as a tuberculous gland. A third growth appeared in the same locality, which was removed by Dr. Van Hook and diagnosed by him as a neoplasm, probably malignant, although it had a capsule.

Microscopic Examination.—A thin, fibrous tissue capsule was seen. No lymphoid tissue could be found anywhere. The whole tumor consisted of a dense network of capillaries, with distinct endothelial walls, surrounded by densely packed mantles of proliferating, round perithelial cells, with distinct nuclei and abundant transparent perinuclear protoplasm. The majority of these cells were arranged concentrically and parallel to the vessel wall, the remainder vertically (Fig. 12).

HEMANGIOENDOTHELIOMA INTRAVASCULARE.

These originate only from blood capillaries, and have been called by Ziegler, hemangioma hypertrophicum; by Nauwerck, hyperplastic capillary angioma; by Borrmann, capillary endothelioma. They consist of a stroma of fibrous tissue with gland-like tubes filled with blood

and lined with one layer of endothelial cells which may be cubical or cylindrical in shape.

Another type of these tumors consists of a stroma of spindle-shaped cells. Irregular or round areas of red blood corpuscles are seen to be enclosed by mantles of endothelial cells which represent the proliferated intima of blood vessels, forming several layers of epithelioid cells. The lumina of these cellular tubes contain erythrocytes or may be entirely obliterated in some portions of the tumor, thus forming solid cords of cells.

OTHER ENDOTHELIAL TUMORS.

All the endothelial tumors are markedly subject to mucoid hyaline and amyloid degeneration, due to cellular metabolic disturbance, which leads to peculiar deposits of these products in the tissues. Hyaline metamorphosis of the vessel walls may lead to obliteration of the vessels, or the hyaline substance may be a degeneration product of endothelial cell masses. Such endothelial tumors are called cylindromata. (Fig. 13.)

Psmmoma and cholesteatoma also are generally classified now with the endothelial tumors but can not be further discussed here.

THE USE OF SHEET PARAFFIN IN LESIONS OF THE NOSE AND EYE.

E. MORAWECK, M.D.
AND
GAYLORD C. HALL, M.D.
LOUISVILLE, KY.

Intranasal operations are for the most part simple procedures and eminently satisfactory both to the patient and to the surgeon. Sometimes following cautery work, however, removal of septal deformities, and even in some cases after turbinectomy, the postoperative swelling is a very troublesome and even serious complication, giving rise to adhesions that may leave the patient in a worse condition as regards nasal respiration than before the operation. As is well known, the reaction following operation varies greatly in different patients—the mucous membrane of some being particularly sensitive to any irritant and intolerant of operative work or even of postoperative treatment. In such individuals the liability of adhesions forming even at a period comparatively remote after operation is a serious possibility.

Some cases are due to carelessness on the part of the patient or to insufficient after-treatment; this possibility, of course, is largely increased in transient patients or those from out of town whose finances or business affairs make more than a very short stay impossible.

It has been our experience that in these cases in which the after treatment has to be left to the patient or to the family physician adhesions are almost sure to follow.

The worst cases are those in which septal outgrowths occur in conjunction with hypertrophied turbinates, and especially when both are operated on with only a short interval between. Several experiences of this kind have made us extremely careful in this particular, and we feel much less anxiety on this account since using the paraffin splint.

We refer to the sheet paraffin and wax used by dentists. The paraffin sheets are five and five-eighths inches long, three inches wide and one-sixteenth inch thick, easily cut and bent in any desired shape and soft enough to conform to the shape of the space in which they are placed.

The accompanying illustrations will serve to show the shape we generally cut them and how they look in position (Figs. 1 and 2). The posterior end is rounded and the edges are smoothed to facilitate its introduction and the anterior end is so shaped by cutting off the lower portion that its end hooks up under the front of the nose, being at the same time invisible at the anterior nares.

The various other devices in use for this purpose leave much to be desired. A long gauze tampon, such as is packed into the nose after turbinectomy, will not be tolerated longer than from twenty-four to forty-eight hours. It is very painful, retains the secretion and is an inviting field for infection. It is after the danger of hemorrhage has passed and the tampon has been

Fig. 1. —Showing splint in position in nose.

removed that the indication for the paraffin splint arises. The splint could hardly exert any influence on the control of hemorrhage except in an extremely narrow nose or by acting as a foreign body, thus favoring coagulation. We have never used it, however, for this purpose.

The Bernay splints, though less disagreeable, are open to the same objections as the gauze tampon. The hard rubber and silver perforated splints are disagreeable and painful; they also do not extend far enough back to do much good in preventing adhesions. The expedient of keeping the postoperative swelling reduced by instillations of adrenalin is in some cases satisfactory, but there are certain disadvantages. In the first place,

Fig. 2. Showing usual size of splint.

the patient is apt to neglect his visits to the office, and often firm adhesion results, though the patient be entirely ignorant of anything wrong.

Neither is it a wise plan to put in the hands of a patient for indiscriminate use a drug of such powerful properties. We have no doubt that it can seriously hinder the regeneration of tissue, and the fact that it has produced local necrosis after use must not be forgotten.

Only common sense surgical principles are indicated in the employment of paraffin. The shape of the splint varies with the area to be separated, being cut to suit each particular case. We handle the paraffin with clean hands and shape it with clean instruments, and as an additional precaution, just before introduction we scrape

the whole surface thoroughly, thus rendering it absolutely sterile.

We have never tried keeping it in solutions of the antiseptics in common use, as in the strength required they would prove an irritant to the mucous membrane, and in any event our method seems to be the most direct and practical.

METHODS OF APPLYING THE SPLINT.

Let us consider in detail some of the ways in which we use this material after it has been prepared as above.

First After Cautery Work.—Practically all this work is confined to the inferior turbinate, and is only done there in selected cases. Immediately after the cautery we apply a hot weak carbolic acid solution to control any oozing; we then use an antiseptic oil spray and introduce the splint as shown in the illustration. It is applied over the full length of the burn, care being taken not to push it too far back as that will produce a choking sensation. The width of the material as supplied being a little in excess of the distance from the anterior to the posterior nares in the adult, in cases where a groove is burned along the entire surface but very little need be removed.

It is best in these cases to have the splints full length, for the patient will speedily inform one as soon as it is too far back; and above all, it is desired to avoid a posterior adhesion, which might happen were the splint too short. After the splint is introduced and it is pushed up in place the anterior end is bent to the septal side and made to conform to that surface, rendering it invisible and more comfortable to the patient. We have yet to find a patient who complained of serious discomfort caused by the splints.

The after treatment is simple. We leave the first splint in for four or five days, having the patient report each day chiefly to see that the splint is in proper position, though in only a few cases have we found that they changed their position. We instill a few drops of weak adrenalin solution wash around the splint thoroughly and follow by an antiseptic oil spray.

As a rule the patient has some breathing space along the sides of the splints and sufficient space to expel the secretions, which, of course, are more abundant than under ordinary conditions. About the fifth day, as a rule, the first splints are removed, the site of operation thoroughly cleansed and inspected and new splints inserted. We do this not only for the purpose of cleansing and inspecting, but also because we have found that if left in longer the splints sometimes break in two, and this we try to avoid, for while not a danger, it is annoying and apt to frighten the patient. This accident has happened several times in patients who did not return for after treatment, and while we have never had any difficulty in removing the different portions, such might happen if the patient should go to some other surgeon, especially as the material we use is exactly the color of mucous membrane.

The second splint also remains in about five days, the patient returning each day or every other day, according to the progress of the case. To be efficient, of course, the splint must remain in position till the membrane is healed. We advise against being afraid of leaving the splint in too long. Very often at the end of four or five days if the splint is removed the space will look clear and free, but if the splint be discontinued at this time and if the patient should remain away adhesions are almost sure to follow. Then, too, there is no particular necessity for haste in their removal. The fact that

we have had patients remain away from the office over a week without any treatment whatever shows that the paraffin splints are very well borne and can in no sense be considered as irritants.

In none of these cases was there any evidence of infection or odor due to retained secretions, despite the fact that the patients had gone so long without nasal cleaning.

Second, After Submucous Resections of the Septum.—In these cases we use the Bernay splints for the first forty-eight hours, after which they are removed and the paraffin cut the shape of the Bernay splints, but slightly longer. The splints are applied on both sides and if necessary held snugly in place by a little gauze placed in the anterior nares, the outside of the splint. This gauze is removed as often as soiled. In these cases, of course, the important point is not so much the prevention of adhesions as the support given to the septum, and the paraffin subserves this purpose admirably (Fig. 3). The after treatment is the same as that given under cautery work.

Third, After Turbinatectomy.—Immediately after the removal of either turbinate, or a part of either, we invariably pack with a gauze tampon, as we have found that to be the only safeguard against hemorrhages, though we have never used the benzoin collodion dressing. This packing we remove, as a rule, in twenty-four

Fig. 3. Showing splints after submucous resection.

hours, or at the longest, forty-eight, and if the nose be very narrow or if there seems to be any chance of the postoperative swelling bringing the raw surface in contact with the septum we insert a paraffin splint as wide as the anterior nares will admit. We are careful, too, just before introducing the splint to remove any tags or shreds of mucous membrane that escaped detection the day before, as it materially assists the repair of the wound.

It is especially important in these cases where the least tendency to the formation of adhesions exists to allow the splints to remain in position till the wound has thoroughly healed, despite the protests of the patient or the number of times it is necessary to change the splint, for it is in these cases that the most extensive and troublesome adhesions occur, despite the fact that the entire turbinate has been removed at the operation. The after treatment is the same as described, though extending over a longer period.

Fourth, In Septal Deformities, Spurs and Ridges.—In these cases, if possible, we do a submucous operation, though even in that case we generally insert a splint, as it holds the flaps of the membrane down nicely and if any has been removed keeps the wounded surface separated from the turbinate. After treatment is the same as detailed above.

REMARKS.

We do not wish to convey the impression that we resort to this expedient after all our intranasal surgery, though we do so very probably in over 50 per cent. We are certain that it has prevented adhesions for us many times when otherwise these would have formed, and it has thus simplified the recovery and saved the patient much discomfort from separating adhesions with a probe each day.

PARAFFIN IN EYE WORK.

We have used this method in our eye work in practically only one condition. In cases in which there are extensive lesions of the conjunctiva, as in burns, and adhesions are threatened, or after operations for symblepharon we have used the paraffin cast.

FIG. 4.—Splints used in eye work.

A piece of the material is shaved down to about half its thickness, moulded over an artificial eye, and a circle cut out in the center so that it does not encroach on the cornea; it is then inserted into the conjunctival sac and allowed to remain there as long as necessary. The cleansing and after treatment can be carried out with very little difficulty and the material is well tolerated. We have used it in this manner in three cases, and in all it proved satisfactory (Figs. 4 and 5).

FIG. 5.—Side view of splints in Fig. 4.

This method of employing paraffin, so far as we are aware, is original. The senior writer of this article conceived this idea while working with Dr. Mueller at the Poliklinik at Vienna and spoke of it to him; owing, however, to the difficulty of obtaining the material but very little opportunity was given for a trial of the method. This was in 1898. Since returning to this country, however, it has been used in our office continually, and its field of usefulness seems to extend. We offer this to those interested in this work, believing it to be a useful device in the class of cases that we have described.

Protection of the Eye in Radiotherapy of the Lids.—The *Revue Gen. d'Ophthalmologie* for January contains a communication from Van Duijse and De Nobele describing the fine results obtained with radiotherapy applied to the eyelids and adjacent parts without fear of injuring the eye. The eye is protected with a shell made like an artificial eye which is placed over the eyeball after it has been anesthetized with cocaine. The shell causes no disturbance while it protects the eyeball completely. It is made of what is called "Paris enamel." Experiments with shells made of metal, glass and other materials showed that they were either irritating or were permeable for the Roentgen rays.

THE MEDICAL DEPARTMENT OF THE ARMY AND THE ADVANTAGES IT OFFERS TO THE YOUNG PRACTITIONER.

COL. PHILIP F. HARVEY, MD.

Assistant Surgeon-General, U. S. Army, Chief Surgeon Department of the Lakes,

CHICAGO.

Medical students and young practitioners should be acquainted with the advantages to be gained by entering the Medical Department of the Army, and a brief survey of the subject may prove of interest and benefit to them, as well as reciprocally beneficial to the service, by drawing to it desirable candidates.

Representatives of the Medical Corps of the Navy and of the Public Health and Marine-Hospital Service have described the advantages to be derived from entering their respective services. While these undoubtedly offer attractions equal in degree to those held out by the Army, it is proper that all sides of the question should be presented in order that a young physician who makes up his mind to enter one of the public services may make his choice according to his taste and temperament. I shall endeavor to give a plain, unvarnished statement of facts concerning the Medical Corps of the Army to enable one to decide intelligently whether or not it will be to one's interest to enter the corps. Very few physicians who receive appointments as assistant surgeons ever leave the service, and it will be discovered that in those rare cases some good business opening in civil life, or the inheritance of a large fortune, or something of the kind, is the reason for their withdrawal. It is also significant that in many, if not in most instances, when men have resigned from the service they have re-entered it at a later date or have endeavored to do so. Two talented and accomplished young medical officers resigned from the Army a short time ago on the strength of flattering offers in civil life, and soon came back asking for readmission, but unfortunately they were barred by the age limit.

The Surgeon-General has had printed a pamphlet entitled "Circular of Information in Relation to Appointment in the Medical Corps," which gives all the data requisite to a complete understanding as to how to get in, pay, emoluments, duties, examination, etc., and can be obtained by request made to the Surgeon-General, U. S. A., Washington, D. C. I shall endeavor to point out to you on this occasion the advantages to be realized from an appointment in the Army based largely on my own experience.

First, let us consider the question from the abstract standpoint of personal advantage to be obtained from a commission. Temperaments and aspirations differ and some men have the idea that the opportunities of an able and ambitious surgeon would be confined within narrow limits by the discipline and subordination required by military life, and that he would have no chance of attaining the eminence offered by the wider field of civil practice. This is an error. An able man has as great, if not a greater, opportunity of rising to fame in the medical service of the Army as he enjoys in civil life. Laveran, a French military surgeon, elucidated the mystery of malaria, and Reed, of our own Army, discovered the cause of yellow fever—two discoveries that have done more to advance sanitary science and to effect the practical reduction of human mortality than any others since Jenner demonstrated the protective power of vaccination. The names of Reed and Laveran are not

the only ones which have been rendered immortal by their work; there are many others. Beaumont, Billings, Otis, Woodward, Tripler and Sternberg are a few whose names occur to me at this moment. Baron Larrey, Esmarch and Longmore are military surgeons whose names are doubtless familiar to you all.

Indeed, in the greater freedom from business cares guaranteed by a fixed salary and in the ampler leisure afforded to the army surgeon by his well-defined duties, the man of scientific inclinations should find greater opportunity for scientific work which should give him reputation and standing than he would be likely to find in the midst of a busy, bread-getting practice.

The question of bread-getting is at once and finally settled for the newly commissioned Assistant Surgeon. But the question may be asked, Would not the opportunities for pecuniary gain be greater in civil life? I will answer, Only in exceptional instances, and it must be borne in mind that life and health are uncertain assets, and that lost health means lost practice and lost income in civil life, whereas in case of disability in the Army the pay goes on, and provision is made for retirement on three-fourths pay in case of permanent disability incident to service or for age. The pay and emoluments of officers are ample for all necessities at first, and later, when increased by rank, it will be found an easy matter to lay by a portion of the monthly pay for subsequent investment. It must be understood that the pay proper does not represent all the income of an officer by any means. In addition to his monthly salary, with its percentage increase from length of service, he draws commutation of quarters at the rate of \$12 a month for each room to which he is entitled, in case he is not furnished with quarters when on duty. His mileage when he makes an official trip without troops is usually greater than his outlay; he buys commissary and quartermaster supplies at the prices paid for them by the government, which is less than wholesale rates; fuel is furnished him at a cost of about one-half the amount his civilian neighbor pays for it; he is entitled to forage for two horses; he is supplied with stationery, and, finally, when he serves outside the continental limits of the United States, he draws an additional increase of 10 per cent. on his pay. In case he is a married man, or has any one dependent on him, he can guard against their future needs by an insurance policy, which during his life he can easily keep paid up. In short, the advantages arising from a fixed income are so many and so obvious that their consideration need detain us no longer.

Consider, for a moment, the difference between the practice of medicine in the Army and in civil life. The fundamental necessity for success in either case is thorough professional knowledge, backed up by some natural ability, but in civil life there is a third qualification which is as necessary as either of those mentioned, namely, business ability. In the Army, the latter is not an important factor, and the surgeon with business ability has no advantage in winning a record for efficiency over his brother officer who is not so gifted. The business side of a medical man in the Army finds its sphere in administrative work, which deals with reports and returns and the control of men, and that is a matter of special training. This is a part of the Army doctor's training that is as indispensable to his efficiency as his professional knowledge, and in certain contingencies even more so. I may remark, in passing, that it is this deficiency in the newly appointed volunteer surgeon,

his lack of knowledge of army methods, that detracts so from his usefulness in war time, no matter how profound his knowledge of medicine and surgery, and which causes disorder and confusion all along the line, with the dire results which we recently witnessed during our brief war with Spain.

In civil life, the physician seeks a practice; in the Army the practice seeks him. In civil practice, the physician must cater, to a certain extent, to his patient's whims, possibly to the degree of administering a placebo; in the Army, the practitioner is at liberty to exercise a somewhat freer hand in dealing with the sick and to follow out his own ideas as to treatment. It is the duty of the Army surgeon to supervise the hygiene of the command and to recommend such measures as he may deem necessary to prevent or to diminish disease; and in doing this well he enhances his value to the government and tends to reduce his own share of professional work.

It may be of interest to those who have had no connection with the military service to hear something about the exact nature of the duties of a medical officer of the Army. The course at the Army Medical School, which all approved candidates are required to attend, includes, in addition to medical, surgical and sanitary instruction, a course of lectures on the duties of medical officers in time of war and peace, property responsibility, examination of recruits, certificates of disability, reports, rights, privileges, customs of the service and transportation of the wounded. On entering on his duties with troops he will at once realize the great value of this instruction and will be enabled to discharge his duties with much greater readiness and ease. There will, of course, be a great variety of medical and surgical work to be done, and opportunities to engage in special work for which the medical officer may be particularly qualified will not be found lacking—for instance, in surgery, in sanitation, in chemical, pathologic, microscopic and bacteriologic investigation, etc.

When the rank of lieutenant colonel or colonel is reached, especially the latter, the duties are almost certain to be of an administrative character, as commanding officer of a large general hospital or as chief surgeon of a department.

Desire to attain the grade of surgeon-general is, of course, a laudable ambition, and the office may be reached by any capable and worthy medical officer who demonstrates qualifications of the proper kind. The office is held by the incumbent as a four years' detail, as it is in the Navy, but the President may prolong the detail. Even should a surgeon-general revert to the grade from which he was promoted, when he reaches the retiring age he is retired as a brigadier-general.

There is another marked advantage which the military service offers to a physician, especially to a young man who is just starting out in his practice. In civil life, the doctor must equip his office with books, instruments and furniture at his own expense; he must buy his own medicines, if he is doing a country practice; pay the rent for his office and furnish the forage for his horse or horses. In the Army, the government furnishes all these liberally and, in addition, all the leading medical journals published in the English language. This effects a very considerable saving in the course of time and is well worthy of serious consideration.

In the military service, one does not have the opportunity of making a permanent home, but is subject to orders and must be ready to shift his *hires et penates*

when his orders come to change station. The allowance of baggage transported at public expense, however, is ample for all practical purposes. A first lieutenant is allowed 6,000 pounds, a captain 7,200 pounds and a major 8,400 pounds. These amounts will cover all articles necessary to housekeeping in the Army, and if the officer is unmarried the allowance will be found much in excess of his needs. Besides this, the government allows a maximum of \$100 for each horse allowed and transported for a mounted officer and also transportation for an attendant. A change of station, therefore, ordinarily can be made without the incurrence of any expense to the officer concerned. His own personal expense for railroad fares and sleeping cars is more than covered by his mileage allowance, as he is allowed a first-class ticket and 4 cents a mile in addition. It will be seen that a move from one post of duty to another is not to be dreaded on account of expense.

Naturally a subject of much interest to an army officer is that of promotion, because with it comes greater authority and increased pay. What is the prospect in the medical department for a satisfactory rate of promotion? At the present time, the organization of the department is not wholly satisfactory in this respect, Congress having added too many officers of the lower grades and too few of the higher grades in reorganizing the corps early in 1901. A new bill, having in view an increased efficiency of the medical department, was prepared by the Surgeon-General two years ago, and at the last session of Congress it was passed by the Senate, and the sense of the House of Representatives was largely in its favor, but the ruling of the speaker blocked its passage. The President, the Secretary of War, the Senate, the Military Committee of the House, the American Medical Association and the country at large are all in favor of the passage of this bill, and the report of the committee of medical officers having it in charge shows that great progress has been made and the probability of securing favorable action at the present session of Congress is most gratifying. This bill increases the higher grades and places the corps on a basis much more attractive to an ambitious young man. Its passage at an early date seems absolutely assured, and, as over 20 vacancies exist at present in the corps, an early entrance is highly important, as promotion goes by seniority, and a stand a few files higher in the list means the attainment of a superior rank a year or two in advance of those who may enter a few months later.

In conclusion, it may not be amiss to say a few words concerning social life in the Army.

Garrison society, as a rule, is very pleasant, and I feel safe in saying that the surgeon will find the officers and their families almost universally delightful people. For the socially inclined young man there is no dearth of entertainment in the way of dinners, card parties, private theatricals, etc., especially at the larger garrisons, so that one need not fear that he will be deprived of the amenities of good society found in civil life.

Variations in Normal Urine. Evans and Moore, as a result of a series of experiments, state that in a normal individual the composition and character of the urine may vary widely within short periods of time, and that even the twenty-four hours' urine may differ considerably from accepted standards for a man of average size. They also state that the urine excreted during the forenoon is in most respects noticeably different from that of other parts of the day. *Montreal Medical Journal*.

THE PHARMACOPEIA AND THE PHYSICIAN.

GENERAL DISINFECTANTS. CHAPTER IX.

General Introduction to the Subject of Disinfectants and Antiseptics.

The important subject of antiseptics embraces so many different agents that are used in such a variety of conditions that any convenient consideration of them according to their uses, or according to the principles that are involved, must necessarily be an arbitrary one. For our purpose we shall consider them under three heads: (1) General disinfectants and antiseptics; (2) local disinfectants and antiseptics, and (3) internal antiseptics. Some substances will require consideration under all three headings, but even this will be found preferable to giving, for example, all of the manifold uses of such an article of mercuric chlorid in one place.

Antiseptics were used long before the causes of fermentation or of putrefaction were known, and it would have been remarkable indeed had man failed to perceive the effect of those substances which are capable of inhibiting a process so commonly encountered. The Egyptians preserved the human body against the attacks of putrefactive organisms, without any evident knowledge of the character of the organisms causing decay, by means of balsams which contained such antiseptics as benzoic and cinnamic acids. The epoch-making discoveries of Pasteur, followed as they were by the favorable reports on the use of phenol, or carbolic acid, by Lister, and the subsequent discovery that other substances possessing great antiseptic power were even less toxic to man, gave tremendous force to the pendulum, which was carried entirely too far by the efforts of well-meaning enthusiasts, and in its backward swing much unnecessary skepticism has been aroused.

While the subject of general disinfection does not necessarily form a part of the physician's daily consideration, there are occasions when he is suddenly confronted with the necessity of erecting such work, and on the thoroughness with which he does it will depend the safety of other members of the community. While there is no great difficulty in securing thorough disinfection, it is absolutely necessary that certain rules be rigidly complied with and this can not be done without an exact knowledge of the object that is to be accomplished and of the means with which the accomplishment is to be brought about. There is probably no condition where a little knowledge can prove to be more dangerous than in this very matter of disinfection, and we therefore have no apologies to offer for going into detail on a subject that may be considered commonplace or well understood.

Sunlight and Heat.

The best of all disinfectants is bright, direct sunlight, coming into immediate contact with the individual germs, not merely shining on one side of a thick garment or carpet, or on small masses of sputum, blood, pus or decaying meat, but shining on and penetrating each individual micro-organism. When this can be accomplished all germs—not all spores—are killed in a few hours. But sunlight is not dependable unless all of the necessary conditions can be rigidly complied with, as may be done with impervious flat surfaces (floors), or linen and other thin garments, both sides of which may be exposed to the direct rays of the sun. The disinfection of articles infected with the more virulent pathogenic organisms usually requires other, more directly active, means than that of sunlight, with the attendant danger of further dissemination, and chemie disinfectants or heat must then be employed.

The direct flame instantly destroys all forms of microscopic life. Dry air, heated to 160° C. (320° F.), kills all disease germs—but not all spores—in one hour; but wood will begin to char at 180° C. (356° F.) and even lower, so that dry hot air is not applicable as a certain means of disinfection in all cases. Simple drying kills bacteria; but masses of sputum or other organic matter may preserve the organisms in their interior for an indefinite period, while spores are thus preserved for years.

Moist heat, water or air saturated with aqueous vapor, heated to 75° C. (167° F.), is rapidly fatal to most bacteria. Water containing typhoid bacilli is rendered much safer by heating to even this comparatively low temperature for ten minutes. Boiling water, on the other hand, will kill even spores in ten minutes or more if they are not protected in small masses. When such masses do exist, 1 per cent. of soda or soap should be added to the water to dissolve the albuminous and other organic matter and at the same time to raise the boiling point slightly. Metallic instruments do not rust in water containing caustic soda, washing soda, baking soda or borax.

Moist steam, or air which is superheated with steam, is rapidly fatal, but superheated dry steam is not so quickly fatal as is the moist at a much lower temperature. Pressure, moisture and increased temperature increase the effectiveness of all methods of disinfection. Moist steam penetrates better than dry air, but heavy fabrics may protect micro-organisms, and particularly spores, for a considerable time, and many articles, such as mattresses, can not be readily disinfected even in this way.

Chemical Disinfectants.

Bedrooms and their contents may be disinfected by the now official:

LIOU OR FORMALDEHYDE.—U. S.—Solution of Formaldehyd, containing about 37 per cent. by weight of formic aldehyd, an oxydation product of methyl alcohol. This substance may be applied directly by washing or spraying, or it may be used in the form of vapor. For the latter purpose the windows and doors are tightly closed, paper being used to stop up the crevices, carpets should be removed or suspended and all drawers and closets opened and their contents so placed that the vapor will readily reach and penetrate every particle of fabric. Formaldehyd solution is then vaporized either in the room or through the keyhole with enough water to saturate the air in the room. Considerable loss of formaldehyd occurs through decomposition during vaporization by heat, and it is, therefore, preferable to saturate sheets with the requisite quantity and suspend them in the room which is to be disinfected, or, better still, the solution may be sprayed from an atomizer. The keyhole is then plugged and the room allowed to stand for from 12 to 24 hours. Novy advises 150 c.c. (5 fl. oz.) of the 40 per cent solution, corresponding to about 165 c.c. (5½ fl. oz.) of the official, for each 1,000 cubic feet of air space. To increase the efficiency of the formaldehyd, 3 liters (3 quarts) of water are vaporized into each 1,000 cubic feet of space. If the atmosphere is damp, less water will be required, of course. Under ordinary conditions it is cheaper to destroy inexpensive mattresses than to disinfect them thoroughly. If they are of straw, destruction is most readily accomplished by burning them out of doors.

LIME.—U. S.—Lime, calcium oxid, constitutes an inexpensive and very useful disinfectant that has a number of widely varying uses. Infected urine, vomit and feces may be thoroughly disinfected by being received into a vessel that contains freshly prepared milk of lime. It is essential that this be freshly prepared, as calcium hydrate rapidly absorbs carbon dioxide from the air and is thereby changed into the inactive calcium carbonate. Milk of lime may be prepared by putting a few pounds of lime into an iron pot and adding about half as much water; the lime rapidly falls into a dry powder with the evolution of heat; to this powder add three times as much water and stir well. The resulting mixture will keep for several days without deteriorating sufficiently to be inert. There are, of course, several precautions to be observed: The lime must be recently calcined, or fresh, and the person who slakes it should be careful to avoid the irritant dust which arises during the process; then, too, the heat generated may be sufficiently high to char wood or to set fire to readily combustible materials. For disinfecting feces or other substances they should be thoroughly stirred with an equal quantity of the milk of lime, or, better still, with twice the quantity, the mixture being allowed to stand for two hours.

Milk of lime is also useful for disinfecting floors, cellars, cesspools after draining, and even walls when they are not subject to injury. It must always be remembered that this

whitewash rapidly absorbs carbon dioxide and thus becomes inert, hence the mixture is an efficient disinfectant, but is not useful as an antiseptic.

Undraked lime is a cheap and very efficient means of destroying animal matter and is also useful for absorbing moisture in damp cellars. As noted before, certain precautions are always to be taken in connection with this really active chemical substance. Cesspools are difficult to disinfect. Large quantities of milk of lime are effective, but the contents must be thoroughly mixed with the disinfectant, whatever its nature.

HYDROCYANIC CHLORIDE OR CORROSIVE.—U. S.—Corrosive Mercuric Chlorid, bichlorid of mercury, mercuric chlorid, or, as it is most commonly called, corrosive sublimate, will be considered more extensively in connection with local antiseptics. It has, however, a number of very important uses in connection with disinfectants.

Corpses of persons dead of an infectious disease should be immediately wrapped in cloths saturated with a 1 to 1,000 solution of mercuric chlorid. The addition of 20 per cent. of glycerin to the solution of mercuric chlorid will prevent the rapid evaporation of the water, which leaves the mercuric chlorid as a dry powder in the cloth. Water which has been used to bathe a person suffering from an infectious disease, such as typhoid fever, should be disinfected by heating to near the boiling point or by the addition of a liberal quantity of milk of lime or a much smaller quantity of mercuric chlorid. If the bathtub is of metal, this chemical should not be used, but phenol or cresol may be substituted.

FERRIC SULPHAS.—U. S.—Ferrous Sulphate, preferably the impure or crude article, commonly called coppersas, is an excellent deodorizer for animal excretions, the iron uniting with the albumin and the acid with the ammonia; it is not a very active disinfectant.

CUPRIC SULPHAS.—U. S.—Copper Sulphate, or blue vitriol, may be similarly used, but it is much more expensive and possesses no marked advantages over coppersas as a deodorizer.

SULPHUR SUBLIMATE.—U. S.—Sublimed Sulphur, or flowers of sulphur, is frequently burned as a disinfectant, in rooms which contain nothing which can be injured by the corrosive action of the resulting sulphurous oxid. It is not so frequently used now that formaldehyd affords a more satisfactory means of disinfection, but it is cheaper and may be used to advantage in cellars and in empty rooms, that can be thoroughly sealed. Hopper-Seyler recommends that 15 gm. (½ oz.) be burned for every cubic meter (cubic yard) of space. This would be equivalent to about 1,500 gm. (3.3 lbs.) for 1,000 cubic feet. Rooms should be left tightly closed for from twenty-four to forty-eight hours, then the fumes of acid still remaining may be readily absorbed by sprinkling ammonia in the room. As with formaldehyd disinfection, the vapor must come into actual contact with the micro-organisms and the atmosphere should contain moisture. This latter requirement is usually met by burning the sulphur in a double vessel, the outer one containing water.

The gas that is generated by the burning of sulphur is very poisonous to man, due to its local corrosive action. Spasmodic closure of the glottis may occur, causing death. Sulphurous oxid, the substance that is thus generated, remains free in mixtures of organic matter longer than free chlorine, hence it is a more effective bactericide.

CAIN CHLORINATA.—U. S.—Chlorinated Lime, popularly, though improperly, called chlorid of lime, is a ready source of chlorine and is a very convenient and inexpensive disinfectant and suitable for many of the purposes for which sulphurous oxid might be used. Chlorin, like sulphurous oxid, is very corrosive, attacking metals, and bleaching and destroying fabrics. Chlorinated lime is useful sprinkled about urinals, damp cellars, outhouses, stables and drains. It rapidly deteriorates on exposure to the air and is not efficient unless it has a very strong odor of chlorine.

The various chlorids that are sold at fancy prices are usually feeble and are in no wise superior to a readily made mixture of a quarter of a pound of chlorinated lime with half a gallon of water. The admixture of an acid at the time of using causes the rapid liberation of chlorine and increases the disinfectant action.

LIGUOR SODÆ CHLORINATÆ.—U. S.—Solution of Chlorinated Soda, the so-called Labarraque's solution, is but another form of a chlorin compound. It has the one advantage of being free from insoluble caustic material.¹

PHENOL.—U. S.—Phenol, the Acidum Carbolicum of the U. S. P. 1890, is much more expensive and not nearly so efficient, as a disinfectant, as:

CRESOL.—U. S.—Cresol has been included in place of the formerly official crude carbohc acid. It is a mixture of the three isomeric cresols, found in coal tar, and is a useful and highly efficient disinfectant and antiseptic.

LIGUOR CRESOLIS COMPOSITUS.—U. S.—Compound Solution of Cresol consists of a mixture of equal parts of soap and cresol. When properly made this mixture is an admirable substitute for any one of the numerous soluble or semi-soluble proprietary preparations containing cresol; such as creolin, cresolin, lysol, lysitol and a host of others too numerous to mention.

Compound solution of cresol is practically identical with the Liguor Cresoli Saponatus of the German Pharmacopœia; it is miscible in all proportions with water, and, as noted above, is a reliable and readily available disinfectant.

One part of the compound solution of cresol added to twenty parts of very warm water is useful for the sterilization of surgical instruments, and a slightly weaker solution, made by adding one part to thirty of warm water, affords an excellent disinfectant for the hands.

POTASSIUM PERMANGANAS.—U. S.—Potassium Permanganate, the chameleon minerale of Scheele, attacks all forms of organic matter and is generally useful for the destruction of foul odors, but is not very useful as a disinfectant. It will be considered at greater length in the succeeding chapter.

The strong mineral acids are destructive to bacteria, but their application as disinfectants is necessarily very limited. As noted before, mercuric chlorid is to be classed with the most powerful of all disinfectants in general use, one part in 10,000 being fatal to spores. Like all other chemical disinfectants, its activity is increased by heat. It precipitates albumin and its activity is, therefore, materially lessened by the presence of any appreciable amount of organic material; this disadvantage of mercuric chlorid may be obviated in part by the addition of an equal amount of sodium or ammonium chlorid (or a small amount of hydrochloric acid), the tablets found on the market for preparing the solution always containing the requisite quantity of one of those salts. As it attacks metals, it is not suited for the disinfection of instruments or metallic vessels. One part of mercuric chlorid in 50,000 parts of water has been demonstrated to possess decidedly antiseptic properties. Its comparative non-volatility, its property of attacking metals and of combining with albumin, and its extreme toxicity limit its field of application, but it remains by far the cheapest antiseptic we have for general use.

Copper sulphate shares with copperas (ferrous sulphate) the power of deodorizing decomposing organic matter though it is but little used for this purpose. It has recently been claimed that the merest traces of copper sulphate, or of copper, in water readily destroy the bacillus of typhoid fever, or at least completely inhibit its growth; even though the copper is present in quantities too small to interfere with the use of the water for drinking. The results of different investigators are not uniform, however, and some maintain that the antiseptic power of copper and its salts has been greatly over-estimated. The soluble salts of zinc, particularly the chlorid, have also been used for disinfecting purposes, but as they

share with copper the disadvantage of being comparatively expensive, without any accompanying material advantages, a more detailed consideration of these substances may be omitted in this connection.²

Clinical Thermometers and Hypodermic Syringes.

The disinfection or sterilization of clinical thermometers and of hypodermic syringes and needles deserves especial mention. With the present comparatively low price of clinical thermometers there is little or no excuse for not having an individual thermometer for at least every patient ill with an infectious or a contagious disease or a continued fever. But even this precaution, desirable as it certainly is, does not obviate the necessity for disinfecting or sterilizing the thermometer. The necessary disinfection may be effected in a number of ways, the thermometer may be dipped for a few minutes in strong phenol, the solution of cresol, or in the now official solution of formaldehyd, after which it is thoroughly rinsed in water. Where an individual thermometer is provided it may be sterilized by keeping the bulb immersed in 75 per cent. alcohol, a saturated solution of boric acid, the official liquor antiseptics, or in a mixture of equal parts of antiseptic solution and of solution of hydrogen dioxide. It must appeal even to the least careful that the disinfection of clinical thermometers is a precaution so essentially important that it should never be neglected.

The hypodermic syringe and needle should be disinfected with strong phenol or cresol solutions, solution of formaldehyd or by repeated washing with very hot water, as a purely routine procedure. When a syringe and needle are known to be infected the disinfection should be as thorough as that of other surgical instruments.

Solutions intended for hypodermic injection can be sterilized by boiling, when this does not cause decomposition. With the now widely used hypodermic tablets it is preferable to boil the necessary quantity of water, or better, distilled water, for a minute or two, then add the tablet, avoiding all unnecessary handling, and heat sufficiently to insure thorough solution. Cocain, being readily decomposed, can not be boiled, but the solution may be sterilized by heating to about 80° C. (176° F.) for thirty minutes on two successive days. It will usually be found to be preferable, however, to use freshly prepared solutions that have been made in a sterile bottle with recently boiled and sterile distilled water. Eucain and stovain solutions may be boiled, but these substances themselves are not entirely free from objections.

Under the subject of internal antiseptics we shall have occasion to mention the disadvantages of sterilized milk, but here we may call attention to the widespread use of formaldehyd, salicylic acid and other chemical antiseptics for the preservation of foods. While we are by no means certain that minute quantities of many of these chemical antiseptics are in themselves injurious, we have ample authority for the opinion that their continued use in appreciable quantities is by no means beneficial. Schmiedeberg regards the constant use of even small quantities of salicylic acid, for a continued period, as unwise in the present state of our knowledge, and Soliman says that the use of formaldehyd can not be too strongly condemned, because of the specific irritation of the mucous membranes which it causes.

The whole subject of food preservatives, however, while it is a vitally important one, and one in which the physician should, and indeed, must be actively interested, is entirely too extensive to be discussed at length in connection with the present series of articles.

1. Where an inodorous deodorant is required it will be found that the Liguor Zinci et Aluminii Compositus of the National Formulary will give better and more uniform satisfaction than proprietary articles of the same type. It is made as follows:

R. Zinc sulphatis, 35 3xxvii 100
Aluminii sulphatis, 35 3xxvii 100
Naphthol 3j 3
Oil of thymol 3j 3
Amp. 4. S. and 3j 3
Water, 4. S. and 3j 3

The salts are dissolved with the aid of heat and the volatile substances added to the solution.

Still another preparation of the same type is the Liguor Zinci et Ferri Compositus, N. F.

2. In this connection we find the following quotation apropos, taken from Wood's "Therapeutics," page 823: "There are not many affairs in life in which the public has been so superabundantly deceived as in the matter of disinfection. A most extraordinary part of this swindling is the case with which distinguished members of the medical profession have given certificates of efficiency and value to comparatively inert and extraordinarily expensive proprietary compounds. Oddly enough, the cat that has drawn the chestnuts out of the fire for avaricious manufacturers has not even had the sense to smell the odor of its own paws when burning." It is evident that Dr. Wood knew less of the resources and the wiles of nostrum makers, and their shrewdness in duping physicians, than he supposed, else he would not think it extraordinary that so many have been deceived.

The subject of preservatives, however, is also of interest in connection with medicines and medicinal preparations. The antiseptic action of alcohol, glycerin, sugar and of volatile oils is well known and generally recognized, while not of sufficient importance to be considered in connection with general disinfection, these substances are widely used as preservatives not alone for medicinal preparations and foods, but also for other substances and materials.

(To be continued.)

Clinical Reports

A CASE OF EPITHELIOMA OF THE FACE.

TREATED BY THE ACTUAL CAUTERY, THE X-RAY AND BY
INCISION.*

J. H. WOODWARD, B.S., M.D.

NEW YORK CITY.

History.—Mr. —, about 70 years of age, presented in the spring of 1903 a small ulceration one-fourth of an inch in diameter in the left side of his face, near the ala of the nose, which had existed more than a year. The area of disease was limited to the immediate neighborhood of the superficial ulceration.

Treatment by Actual Cautery.—In May, 1903, I burned it out with the galvanocautery. The wound so made healed promptly without incident, leaving a small, smooth cicatrix.

Treatment by Röntgen Ray.—In November, 1903, ulceration in the cicatrix had begun. Influenced by the very favorable published and verbal reports of the beneficent effect of the Röntgen ray in curing epithelioma of the face, I referred my patient to a very competent surgeon, thoroughly familiar with x-ray therapeutics, for treatment by that method.

Report.—To him I am indebted for the following notes of the case while under his care:

"On examination I found a spot about as large as a small, ordinary white bean about three-quarters of an inch beyond and above the ala of the nose, left side. The outer half had healed, the inner part was ulcerating. There was very little induration on the floor and sides of the ulcer. He came to me November 4 and received about three treatments a week until Christmas, making in all twenty-two exposures. The treatments were made with a medium-sized tube, medium vacuum, at a distance of six inches, with an exposure of ten minutes; the face, head and chest were protected by plates of lead and tinfoil. The tube was influenced from a 12-32-inch plate, Wait & Bartlett static machine. Very little effect was observed after four weeks' treatment. The ulcer seemed to have some source of irritation. This was found to be too frequent examination with the finger. The ulcer was then protected with a cotton or rubber tissue and collodion dressing, which was removed during the exposure to the rays. The effect was magical: the ulcer closed at once and remained closed. At this time a lead glass tube, with a terminal diameter of one inch, was used for the remainder of the exposures. This was placed within half an inch of the diseased surface, with an exposure of five minutes. After an interval of two weeks (i. e., beginning Jan. 12, 1904), four more exposures were made at intervals of three days in order to make sure all diseased tissue was destroyed."

The x-ray treatment, therefore, practically extended over a period of three months and was thoroughly and painstakingly given by a conscientious operator.

Treatment by Excision.—Early in April, 1904, or a little more than one month after the last x-ray exposure, the patient came to me for re-examination. Ulceration had again broken out in the cicatrix. At this time I was strongly tempted to do only a curettage. Fortunately, however, my suspicions had been sufficiently aroused, and on April 6 I extirpated the growth. The operation was made through what appeared macroscopically to be healthy integument at a distance from

the apparent disease down to healthy periosteum and healthy perichondrium. The latter was curetted away, because it lay in rather close proximity to the ulceration. The resulting wound was at least one inch in diameter and nearly circular. It was allowed to heal by granulation in order to facilitate later the detection of any cancerous tissue that might have been overlooked, and had closed completely by May 7, leaving a small, smooth scar.

The excised tissue was taken to Dr. F. E. Sondern for examination, with the especial purpose of ascertaining whether the operation had included the entire diseased area. He reported as follows:

"The cut specimens show a typical picture of epithelioma. Between the lesion proper and the periphery of the specimen there is an area of normal epidermis, the corium showing a small amount of round cell infiltration only. Very near to the periphery, however, the epidermis shows an irregular downward growth into the corium, which shows a decided inflammatory reaction. This looks like an early stage of the disease at the periphery of the specimen."

Further History.—I was surprised to find that the microscopic examination had revealed a more diffuse cancerous infiltration than had been supposed possible in this case. The operation had not circumscribed the growth.

On May 14, 1904, a small collection of pus about the size of a pinhead had developed in the part of the cicatrix nearest the inner angle of the eye. This was evacuated and the small cavity treated with pure carbolic acid. On May 16 the same spot was curetted and in two days the wound had healed.

On June 1, 1904, suppuration had recurred in the same place, and on June 3 the upper portion of the cicatrix and half an inch or more of integument between it and the inner angle of the eye was cut out. This wound was closed by three sutures and healed by primary union.

Report.—Dr. Sondern reported on the excised tissues as follows: "The cut specimen shows a typical picture of epithelioma. There is a proliferation downward of epithelial invaginations into deep tissues and numerous epithelial pearls. There is also some inflammatory round cell infiltration of corium and deeper tissues."

On Oct. 5, 1904, the cicatrix was almost invisible and nothing pathologic was discoverable in the wound region. In November, 1905, eighteen months after the last operation, his only symptom was itching in the cicatrix. I was not able to discover anything pathologic in or about the scar, which was almost invisible, smooth and not adherent. The adjacent skin was normal. Inasmuch as a scar on his forehead carried for many years itches more or less, that symptom in the operation scar may be of no importance.

In May, 1903, the ulceration appeared as innocent as an epithelioma can, and it seemed a simple matter to effect a cure with the actual cautery. A more favorable case for treatment by the x-ray than this was in November, 1903, could not be imagined. Naturally, it is not possible to state exactly how far the disease had infiltrated the skin prior to the x-ray treatments, but macroscopically the disease was limited to a very circumscribed area. After the x-ray exposures, however, it was clear not only that there had been an absolute failure to cure, but that the area of disease had increased considerably. Possibly the actual cautery had acted as an irritant, inasmuch as it had not been applied with a sufficiently free hand to kill all the cancer cells. It is certain that the x-ray had operated as an irritant, causing the disease to spread more rapidly in every direction than it would have done if undisturbed. The lapse of time alone does not account for the marked changes in the conditions, especially those that occurred between November, 1903, when the x-ray treatment was begun, and April, 1904, five weeks after the last x-ray exposure had been made.

Experience in this case teaches that the ancient and honorable method of early and complete excision should have been the method of choice. Objection to excision

* Read before the Society of the Alumni of Bellevue Hospital.

of growths about the face is urged on the assumption that noteworthy disfigurement is a necessary consequence of cutting operations. We know that such arguments are not valid when excision is made in the incipency of the disease. In all other cases the question of cure is paramount.

A remedy for cancer that is lauded because its application does not disfigure the patient must possess curative properties superior to any other known treatment to entitle it to respectful consideration. In this case, the history of which has just been related, the *x*-ray proved to be not only a dismal failure as a cure, but it was positively harmful, both in wasting time and in stimulating the cancer's growth.

Bodine's method of using cocain locally enables the surgeon to avoid the objection to, and the dangers and disagreeable features of, general anesthesia, and promises the practical certainty of a painless operation. In my patient's case a positive history of attacks of true angina pectoris was an important factor. It seemed advisable at the operation of April 6, 1904, to give the patient a hypodermic of morphin before injection of the cocain solution was begun, because it is the systemic antidote to cocain and also the most potent agent we may employ in angina pectoris. This precaution was probably unnecessary. In the second cutting operation the use of morphin was omitted. In both instances no untoward cardiac symptoms were observed either during or subsequent to the operation.

58 West Fortieth Street.

A CASE OF SYPHILITIC DACTYLITIS OF THE TOE.

ASTLEY PASTON COOPER ASHURST, M.D.

Surgeon to the Out-Patient Department of the Episcopal Hospital, PHILADELPHIA.

Patient.—R. E., aged 40, applied to the surgical dispensary of the Episcopal Hospital April 20, 1904, for treatment of his left foot.

Examination.—The foot was moderately swollen, with two areas of superficial ulceration on the dorsum, and with the middle toe the seat of a swelling so typical of syphilitic dactylitis as seen in the fingers, that the specific nature of the lesions was readily determined. The patient stated that the ulcerations of the dorsum of the foot had persisted more or less in their present form for a period of eighteen months and that the toe had been in its present state for about six months. He had tried various salves and ointments, but so far no form of application had proved of any avail. On further inquiry it was learned that twelve years previously the man had had a sore on the penis, which, although accompanied by suppurative inguinal buboes, was nevertheless followed later on by an evanescent skin rash. Anti-syphilitic treatment had been employed for about six weeks. The accompanying illustration, kindly made for me by Dr. R. S. Hooper, shows very well the appearance of the foot and toe when the patient came under my treatment.

Treatment and Result.—The ulcers were dressed locally with dilute citrin ointment, and iodid of potash was administered internally. Improvement was rapid, the ulcers healed, and the dactylitis disappeared, so that in the spring of 1904 the foot was practically normal. I heard from this patient in November, 1905, and learned that he has taken the potassium more or less regularly ever since being under my care; he says he learned by experience that soon after stopping the medicine he was prone to develop ulcers or sores in some part of his body. His foot has given him no further trouble.

Syphilitic dactylitis was first accurately described by Dr. R. W. Taylor,¹ of New York, in 1871. The affection

had been alluded to previously by one or two writers, but it had never before been fully studied. When Van Harlingen, in 1882, wrote the article on "Syphilis" for the International Encyclopedia of Surgery, he could find less than twenty-four cases of the affection recorded. It occurs in two varieties: The more common variety affects the subcutaneous tissues and the fibrous structures of the joints; the other arises in the periosteum and the bones. It does not, as a rule, make its appearance until five to fifteen years after the primary lesion.

Syphilitic Dactylitis.

It appears to be distinctly rarer in the toes than in the fingers. I have observed two cases of syphilitic dactylitis of the finger in the dispensary of the Episcopal Hospital, one being a manifestation of hereditary syphilis in a child, the other occurring in an adult. In the finger it is nearly always the proximal phalanx that is affected; but in the toe, as is evidenced in the case here-with recorded, the swelling usually extends throughout the whole length of the affected digit. As remarked before, the appearance is characteristic, and even if no syphilitic history could be elicited I think the true cause of the lesions would be readily determined.

OSTEOMA OF THE OUTER SURFACE OF THE ULNA.

C. B. CLAPP, M.D.

Surgeon in Charge, Wabash Employes' Hospital.

MOBERLY, MO.

Patient. J. S. H., aged 28, section laborer, when about 10 years of age noticed a small lump on the outer surface, near the lower end of the right ulna, which has slowly yet constantly grown until the present time. He does not remember any trauma to this part at any time.

Description of Tumor.—The tumor itself measures $7\frac{1}{2}$ inches in circumference; its surface is rough and jagged, resembling the cauliflower somewhat in appearance. The radiograph (Fig. 1), which was taken by me before the operation, shows clearly the usual shortening of the shaft of the ulna and the drawing away of its articular surface from the wrist joint. It also shows the peculiar curving of the shafts of both the bones of the forearm, compensating, in part, for this development, and also the malposition of the distal extremity of the ulna. Since

¹ Amer. Jour. Syph. and Derm., 1871, vol. II, p. 1.

the operation the distal piece has acquired a more normal position and will doubtless adapt itself more closely to the wrist joint in time and thereby afford material strength.

Remarks. It is interesting to note that this man has always done the heaviest kind of manual labor, using the shovel constantly for days, driving spikes with a heavy sledge, lifting

Fig. 1. Showing the shortening of ulna and malposition of articular surface.

steel rails, handling ties, and all work usually done by a man on the section, and at no time, either before or since the operation, has he noticed that this wrist or arm tires before the other, or is weaker than the other.

New Instrument

A NEW ANOSCOPE.

T. CHITTENDEN HILL, M.D.

Surgeon to the Rectal Department of the Boston Dispensary.
BOSTON.

This new instrument, which I devised for a special case, has proved of such general utility in the treatment of affections of the lower rectum and anal canal that a brief description of it may be of interest:

For examinations and treatment of the rectum proper and pelvic colon the round tubes of Kelley and the later pneumatic modifications of these leave nothing to be desired but for the treatment of ulcerations, abrasions, new growths, etc., of the anal canal the specula in common use have not at all times been satisfactory. A diagnosis can be made by digital examination, but it is often important to have a good view of

the lesion in making local treatments. With this simple instrument I have treated many patients who otherwise would have been obliged to undergo general anesthesia.

It consists, as the cut shows, of a straight glass tube with an oval window in the side. The lower end is rounded and punctured by a small hole which allows air dilatation of the rectum. The handle is detachable and to prevent cracking of the glass it should be removed when the instrument is sterilized.

METHOD OF USE.

With the patient either on the elbows and knees or in the right semi-prone position the distal end is smeared with vaselin and pressed firmly over the anal orifice. Then as the patient strains down the instrument slips easily past the sphincters.

Should there be an excess of vaselin about the window in the instrument it is wiped away with a cotton swab. By gently rotating and partially withdrawing the tube the whole anal circumference can now be thoroughly explored without discomfort to the patient.

ADVANTAGES.

The following advantages are claimed for this speculum over

others now in use: The round tube is the most easily introduced when there is spasm of the sphincters, which is nearly always the case in disease in this locality. The edges of the oval window are so smooth that rotating and withdrawing it does not pinch the mucous membrane and thus cause pain; and what is more important, the mucous membrane anterior to the part being examined is firmly supported and thus a good view is obtained.

In the bivalve specula and the conical fenestrated ones with removable blades, the mucous membrane so prolapses into the instrument that a satisfactory examination is often impossible. Besides, their use is painful and they have to be reintroduced several times in order to examine thoroughly the whole of the anal canal.

When necessary for special cases the window may be enlarged, made smaller, or placed at a different level. The one in the cut, however, has proved suitable for nearly every case.

This instrument I now use almost exclusively when a speculum is required for the examination or treatment of the anal canal. And when it is recalled that more than half of the diseases of the rectum are in this locality its field of usefulness is readily appreciated.

Milk in Pulmonary Tuberculosis. When any dyspepsia arises from the use of milk, Burton-Fanning advises adding 20 grains (an egg-spoonful) of sodium bicarbonate to each tumblerful. The milk may also be given warm, or thickened with some farinaceous food, or it may have a little spirit added. It should not be swallowed in bulk, but should be slowly sipped. With these modifications milk usually agrees, even when drunk at meals with other food. A great deal of milk can be administered in the form of junket or other pudding, to which cream may be added. *Danvers Medical Times*

PROTECTION THROUGH NATURAL SELECTION.

There is an almost universal impression existing with special force among physicians that unsuitable hygienic conditions, and especially the influence of widespread disease, in the course of time, brings about degeneration in a race subjected to them. It is not a little surprising, then, to find that an article expressing exactly the opposite ideas has been written by a distinguished student of heredity, whose observations have extended over a long period of time, and who is known as a conservative writer, not lightly to be tempted to express exaggerated notions contrary to usually accepted ideas, merely for the sake of attracting attention. In an article on "Heredity and Social Problems," Dr. G. Archdale Reid, a fellow of the Royal Society of England, who last year published a book on "Principles of Heredity" that attracted widespread attention, insists that there is conclusive evidence of the errorneousness of the belief that the conditions under which parents live "are a potent cause in variations in offspring subsequently born," and of the mistakenness of the persuasion "that parental ill-health, due to disease, intemperance, bad sanitation, want, hardship and the like, tends to alter the nature of children in such a way that they are rendered innately degenerate."

This is a contradiction, direct and absolute, of the opinion held by many physicians, and consequently Dr. Reid's arguments for his conclusions are worthy of serious consideration. He calls attention particularly to the fact that long-continued exposure to a disease, far from bringing about degeneracy so that the people thus exposed become more liable to it, on the contrary, always leads to the production of a special resistive vitality which enables the exposed people to combat the particular affection to better advantage. Negroes on the west coast of Africa, for instance, have been exposed for hundreds, perhaps thousands, of generations to severe malaria. Practically every negro suffers from the disease and many perish. "No one will say, however," says Dr. Reid, "that the negroes are degenerate. On the contrary, they are a tall and robust race, and, as is well known, every race exposed to the disease is resistant to it precisely in proportion to the duration and severity of its past sufferings." The large number

of deaths that have occurred by a process of natural selection has eliminated the unfit. The survivors are not degenerates, but are superior to what they would have been had there been no malarial racial selection.

The same thing holds true for many other races and for many other diseases. Europeans who have been longest exposed to consumption and have suffered much from the disease are more resistant to it than the negroes, to whom tuberculous exposure is a comparatively recent incident in history. Our American statistics seem to bear out this fact very completely. Still best resistant to consumption are the South Sea islanders, who have had no previous experience of the disease and are exterminated by it when it once gains a hold. Tuberculosis, when first introduced among the American Indians, was much more fatal in its effects than it is at present, as, indeed, were all of the contagious diseases. The Indians still continue to fall victims to these diseases much more readily than the white man, but that seems to be precisely because of the shorter time to which the race has been exposed to them. When America was discovered, except for malaria and yellow fever, we know of no infectious diseases that existed on this continent.

Even more interesting is it to find that in matters usually considered as belonging to the moral side of nature, a race more or less immune seems to be produced by natural selection. The nations which for the longest periods have been freely accustomed to the use of alcohol are those in which there is at the present moment the least intemperance. Many races, as Dr. Reid says, have been afflicted by alcohol for thousands of years; none has become degenerate. Some men are naturally more susceptible to alcohol than others; these, because they are more tempted, drink to greater excess and so are weeded out. As a consequence, every race possessed of abundant supplies of alcohol is temperate in proportion to its past experience of the poison. The inhabitants of the wine countries of Europe are very temperate; the inhabitants of northern Europe are much less temperate. Savages, who have had little or no experience of alcohol, are the most intemperate of all when afforded the opportunity. Nearly the same thing is true of opium. The natives of India who have longest used opium are now least harmed by it and are temperate in its use. The Chinese are less temperate. The Burmans and Polynesians, to whom it has only lately been introduced, are extremely intemperate in its use.

In a word, Dr. Reid ascribes racial improvement generally to the same protective mechanism as that through which immunity to disease comes. The body learns to resist, and only such individuals as are capable of resistance survive to be the procreators of a race that will have in itself the perpetuated elements of such resistance. Dr. Reid's paper is discussed in the same issue of the *Independent* by two prominent American authori-

ties, Professor Franklin H. Giddings, of the department of sociology of Columbia University, and H. W. Conn, professor of biology in Wesleyan University, who both agree that the influence of environment on the race has been very much overrated, and that natural selection and the elimination of the unfit are undoubtedly the saving factors in present-day human evolution. The consideration of such opinions should open up new lines of thought to physicians who are apt to cling to the idea that racial degeneration is a question of unsuitable environment rather than of the preservation of the unfit to such a degree that degenerative factors are not eliminated, as they would be in the ordinary process of human nature.

THE ETIOLOGY OF HEMOPHILIA.

Since hemophilia, superficially at least, seems to depend on some alteration in the coagulability of the blood, it is frequently regarded as an example of the hereditary transmission of a chemical peculiarity. The exact cause of this peculiar tendency to prolonged bleeding from insignificant or perhaps imperceptible wounds has been sought vigorously by both histologic and chemical means, but as yet without avail. Various observers have described abnormal thinness, or increased cellularity, or fatty degeneration of the vessel walls, but the findings have been far too inconstant to afford a satisfactory anatomic explanation of all the features of hemophilia. Likewise, increased blood pressure can be ruled out, for, although the left heart is frequently enlarged, usually no increased pressure is demonstrable; furthermore, conditions of high blood pressure, such as nephritis, do not cause hemophilia. The theory of "hydraulic plethora" is also without good foundation.

The most natural place to look for the fundamental fault is in the blood, but speaking strongly against this is the frequent occurrence of "local" hemophilia, *e. g.*, in some hemophilics wounds of the skin may behave as in normal individuals, whereas any injury of the mucous surfaces is followed by pronounced hemophilic bleeding¹; in other cases the hemophilic bleeding is limited to regions above the shoulders; in still another class the bleeding is always from one organ, *e. g.*, the kidneys. Nevertheless a great deal of investigation of the blood has been done, chiefly with negative results. There are no characteristic changes in the cellular elements of the blood, beyond those common to all secondary anemias, except, possibly, Sahli's observation of a decrease in the number of white corpuscles, with a relative increase in the number of lymphocytes. No constant alterations in the salts of the blood have been found; and the proportion of water, the alkalinity and the osmotic pressure of the serum all seem to be normal. Since bleeding is normally stopped principally by coagulation, a deficiency in fibrin or its antecedents might be expected, but most studies on this point have shown a normal

amount of fibrin in the blood of hemophilics, the frequent formation of large tumors of clotted blood at the bleeding points supporting the experimental evidence that the blood contains an abundance of fibrinogen.

As to the rate of clotting, the results obtained by different observers are by no means in accord, which seems to be explained by the recent studies of Sahli,² who has avoided a number of errors made in earlier investigations. He found that in the intervals between the attacks of hemorrhage the rate of the coagulation of the blood is constantly much slower than normal. During an attack of bleeding the coagulation time approaches the normal; indeed, it may be quicker than normal; apparently this is due to a reaction on the part of the organism to the loss of blood. If blood be collected directly from the site of bleeding, the coagulation time is very rapid, because of the accumulation of fibrin ferment from the clot over which the escaping blood flows. Yet, in spite of the normal coagulability of the blood, and the rapid clotting after the blood escapes from the vessel, bleeding continues for long periods before it can be stopped. As there is no general change in the properties of the blood to account for the bleeding, and as local influences seem to be important in hemophilia, Sahli advances the plausible hypothesis that chemical changes in the vessels must be the essential factor in hemophilia. Hemorrhage is ordinarily checked chiefly by the formation of clots that plug up the bleeding vessels at the point of the hemorrhage. The local formation of the clot is believed to be due to liberation of fibrin ferment (or its antecedents) by the injured cells of the vessel wall at the point of the vascular lesion. If the cells of the vessel wall are deficient in these fibrin-forming substances the blood will not clot in the mouths of the vessels, but will first clot when it reaches a place where fibrin-forming substances are furnished by other tissues, or, as is generally the case, when the leucocytes are broken up by exposure to the air or other injurious influences. Under these conditions the blood may clot in large masses, but, as there is no fibrin adhering to the vessel walls at the bleeding openings, blood continues to escape.

Sahli considers, therefore, that the cause of hemophilia lies in hereditary deficiency of fibrin-forming substances (thrombokinas or zymoplastic substances) in the vessel walls, so that when the vessels are injured there is no local production of fibrin such as occurs normally. Local hemophilia may be explained readily as a local deficiency in fibrinoplastic material. In general hemophilia even the leucocytes may exhibit the same defect, in which case clotting of the blood is diminished even outside the tissues. This hypothesis seems to be in excellent agreement with the facts now known, but it yet remains to demonstrate such a lack of fibrin-forming elements in the vessel walls and other tissues of a hemophilic subject. It probably also explains why the marked

¹ A. Abelschaden: Ziegler's Beft., 1904, No. 35, p. 213.

² Zeitf. f. klin. Med., 1905, vol. lxi, p. 261. See also THE JOURNAL, May, page 1817.

increase in coagulability of the blood that can be obtained by administration of calcium salts is, as Wright's observations show, not sufficient alone to stop hemophilic bleeding, even although the rapidity of clotting is much greater than normal. As Sahli suggests, whatever means are employed to check such bleeding, should aim to secure a stoppage of the mouths of the vessels by the clotting blood; this may be best attained probably by applying the styptics under considerable pressure.

THE RESPONSIBILITY OF THE MEDICAL SCHOOL FOR CONTRACT PRACTICE AND OTHER EVILS.

We have often referred to contract practice and its causes, and we have included in the latter the overcrowding in the profession, the jealous rivalry and the disorganized condition that permits men to isolate themselves and to minister to the immediate present at the expense of the unthought-of future. Perhaps we have never dwelt with sufficient emphasis on the part which the medical college plays in failing to lay a foundation in the physician's training that will tend to prevent secret division of fees, contract practice, jealousy, slander and various other unethical practices.

One of the ways in which most, if not all, of our medical schools have failed to do their duty has been in graduating students into professional life without having given them the slightest idea of the economics of medicine. No word of those principles of ethics which should govern the conduct of medical men has been taught them. Medical students have had no instruction on what should be their relations to their fellow-physicians and to the profession in general or to the people whom they are to serve. Thus, ignorant of what they should know, they step into professional life and at once begin to make blunders. Who of us can truthfully say that, during the earlier years of his professional life, he did not do many things which were not in accord with that spirit of honor which should have guided him, and this solely because he knew no better? Not only have the colleges failed to teach the student what should be his future attitude toward his professional brethren, what he should do and what he should leave undone, but they have also failed to instill into the student's mind that spirit of "Unity, Peace and Concord" which he most needs.

Indeed, so far from teaching this, our schools have too often placed before the student, throughout his entire course, living, breathing examples of "envy, hatred, malice and all uncharitableness." Who of us can not recall the bitter rivalry, the unseemly fights and squabbles between the members of the faculties of his own school and some other, or between those who were members of the faculty and those who would like to have been?

Having been graduated in ignorance, the physician

has begun his lifework in the greatest of all liberal professions, heavily handicapped. The seeds of discontent, of jealousy, of discord, have been sown during his undergraduate years, and they are not healthy seeds to plant in isolated soil. Until very recently, and in large measure even now in many sections of the country, he has found himself a solitary member of an unorganized profession; he has gone his own way and been subject to the evils that accompany a solitary life. His professional neighbors, without knowing him or his ability, have not welcomed him to their ranks. There has been no society of medical men where he might meet his professional brethren and thus counteract the individual peculiarities which develop in all of us. He has been slandered, and, in turn, has quite as unjustly slandered his fellow-practitioners while the people have looked on and their respect for the profession suffered. Whole communities have been disturbed for years, and children have been born, have grown up and gone into the world, carrying a feeling of contempt for the medical profession, simply because a few otherwise good physicians and excellent men could not dwell together in charity. And probably the foundation for most of these life-long, bitter fights among medical men has been a falsehood.

Much—not all, of course—of this could have been avoided had the young physician been warned in time.

THE EXPERIMENTAL PRODUCTION OF ARTERIO-SCLEROSIS.

The study of disease in the human being is always rendered difficult by the fact that the pathologic investigations, for the most part, must be limited to the terminal stages of the disease. Such studies, while they doubtless advance our knowledge to a large extent, throw little light on a very essential aspect of the subject, the evolution of the disease. In man we must depend for our studies of the early stages of most chronic diseases on the chance finding of early lesions in subjects dead of other conditions. Even here the pathologic conditions may be so various that their inter-relations are difficult of interpretation, and we are finally reduced to the experimental method if we are to follow a given disease, uncomplicated, throughout its course.

Arteriosclerosis is a disease so common and so varied in its effects that it has always been subjected to close study and numerous attempts have been made to produce it experimentally. Up to within three years such attempts have been uniformly unsuccessful. In 1903, however, Josué described lesions in the aorta of rabbits, similar to those found in man, and due to the administration of the active principle of the adrenal glands. His report has since been confirmed by various observers, recently by Pearce,¹ and the original observations have been considerably extended. The lesions of experimen-

¹ Wright & Bell, *Med. Jour.*, 1891, No. 2, p. 57.

¹ *Jour. of Exp. Med.*, 1906, vol. VIII, p. 74.

tal arteriosclerosis in the rabbit, and this seems to be the animal *par excellence* for its experimental production, are remarkably like those which occur in man under natural circumstances. The disease differs in some respects from human arteriosclerosis. It is confined to the aorta, according to Pearce and most observers, though it may attack other vessels, according to Erb. The acuity with which the lesions appear (they are often well marked after two months) would also seem to be different from the usual course of human arteriosclerosis. To the naked eye, the animal and the human disease are practically identical. The vessels of the rabbit show, first of all, an irregular longitudinal streaking of the intima, later irregular, discrete or confluent areas of a pearly gray color, and almost constantly calcified, later still dilatations, even aneurisms, with more marked calcification, appear. It can readily be seen that just such a description also fits the lesions of human arteriosclerosis.

The greatest interest of these experimental arterial lesions lies in the histologic findings. Pearce's work especially shows that the earliest lesions are in the media and affect the muscular tissue and the elastica. The lesions are degenerative in character, partake of the nature of a necrosis, and are followed by the deposition into the necrotic tissue of lime salts. Fracture of the elastic fibers, which is quite commonly seen, occurs least where the deposition of lime salts is greatest, and is seen to the largest extent in connection with aneurismal dilatations where but little calcification has occurred. The proliferative changes in the intima which occur during the later stages of the process seem, according to Pearce, to partake very differently of the nature of a compensatory process.

The method by which adrenalin acts in producing these changes is still obscure. That the action is due to the direct effect of toxins on the media seems unlikely from its limitation to the aorta. That it is due to the action on the vasa vasorum, as Erb holds, seems doubtful in the presence of changes in the adventitia. The most striking change produced by adrenalin is the increased blood pressure, and some, at least, of the changes observed might be due to this. As Pearce points out, this aspect of the question must be settled by methods other than histologic.

So far as applying the results of these experimental studies to man is concerned, most of the investigators have taken a conservative stand. At present, pathologists are pretty well divided as to the pathogenesis of arteriosclerosis. There are many who hold that the disease is essentially an inflammatory one and that the intimal changes are not secondary to the medial ones; on the other hand, many still support Thoma's view that the first changes are degenerative ones in the media, and that the intimal changes are of a compensatory nature. The experimental work seems to give support to the latter view.

PHYSICIANS AND POLITICS.

It has long been regarded as a kind of unwritten law by physicians that they should take no part in politics. Perhaps, however, this is scarcely the correct way in which to describe the situation. Rather might it be said that physicians, as a body, have shown themselves apathetic in regard to politics, preferring to stand aloof from party strife and to look on the whole question as one in which they had slight concern.

This attitude of indifference has been rudely shaken of late years, and the fact is being borne in gradually on medical men that, in order to protect their own interests and the interests of the general public, they must abandon this lethargic position and act both aggressively and defensively. There are many reasons why the physician should not eschew politics; indeed, there are more reasons in favor of the physician playing his part in the political world. The somewhat cynical indifference assumed by the medical profession toward politics has resulted in the passage of many measures in several states inimical to physicians and by no means advantageous to the community at large. Signs are not lacking that a change of front is about to be manifested by medical men, and that in the not far distant future the doctor must be reckoned with as a power in politics. This is as it should be. It is not urged that the physician should inject himself into the hurly-burly of political warfare, but that he should use his influence to forward such measures as would be conducive to the betterment of sanitary conditions and to oppose measures calculated to be detrimental to the public health.

If the medical man wishes, he can exert an immense amount of influence. He is, in a general way, educated, well read, a good judge of human nature, and, above all, is in closer touch with all sections of the community than are the members of any other class. It goes without saying that, as regards matters that come within his particular province, he is entitled to speak with authority. It has also been suggested that by the participation of medical men in politics the tone would be raised. At any rate, municipalities and governments would often do well if they asked for and acted on expert medical opinion ere embarking on many of their wide-reaching schemes. As it is, the fact stares us in the face that the aid given by the government to medical or sanitary measures has been meager in the extreme. The medical man is a negligible quantity in the affairs of the nation or state, and until he has shown that he is an important member of the community politically he will, as before, be treated with contemptuous indifference. The upshot rests with himself to a very large extent.

THE PREVENTION OF BLINDNESS.

If it be true, as stated, that 33 per cent. of blindness is certainly avoidable, it becomes pertinent to consider whether the profession can do more, both in the care of eye affections and in the education of the public.

In a small proportion of cases, blindness is caused during infancy, but in the majority it must be attributed to the more dangerous, and especially to the contagious, eye affections, concerning which the public is too little informed. There is no disability that is in its way more discouraging to the individual or more costly to the public than blindness, and, while it is possible to render it less of a public and private burden, very much still remains to be done. The evil is none the less serious because a considerable portion of the burden is borne by private resources instead of public charity, as is the case with insanity. The fact that the blind are not so much a public danger does not render them less deserving of public sympathy or make it less our duty to ease and especially to prevent the occurrence of their infirmity. Much can be done by the promotion of proper legislation, as in the state of Massachusetts, and still more by an increased sense of responsibility and conduct in accordance throughout the medical profession. We are doubtless doing much both personally and in the education of the public, but the existence of so much preventable blindness means that we could do more.

PHYSICIANS DO NOT APPROVE OF CHLOROFORMING THE HELPLESS.

The astonishing allegation has been quoted in a number of newspapers recently that two medical societies had indorsed the proposal to chloroform all persons who had reached the age of sixty. All sensible physicians knew this could not be true of any reputable society, and we at once wrote for information. The secretary of one of the societies says it was all the result of a joke on a reporter, who accepted as truth the fabric of lies and embroidered on it to a considerable extent in his paper. We hope that the affair has not contributed to the public's distrust of the physician. We had supposed that the unenjoyable notoriety thrust by a dull-brained press on the originator of the chloroforming-the-aged joke would be a solemn warning to all other physicians to avoid the subject. If one insists on joking, let both joke and listener be approved by a state board of examiners in humor.

THE POSTOFFICE DEPARTMENT AND MEDICAL LEGISLATION.

The influence of the Postoffice Department in regulating, if not actually controlling, the sale of spurious drugs and medicines and appliances for criminal purposes is of the highest importance. It is a source of congratulation that the present Postmaster-General, Mr. Cortelyou, is fully alive to this fact, as is shown by his letter published in the Department of Medical Legislation. The thanks of the medical profession and society in general are due to the Postoffice Department for having suppressed many concerns that have been engaged in this nefarious traffic. It is a matter of sincere regret, however, that the present law does not enable the department to deal summarily with many of these offenders. Congress should so amend existing legislation that it shall be an offense to deposit in the mails matter advertising either remedies, appliances or treatment intended

for fraudulent or criminal purposes and authorizing the confiscation of the same when found in the mails. The assumption of the Postmaster-General that such a law would have a most wholesome moral effect will be ratified by every reader, who will likewise agree in the view that society in general is entitled to precisely this sort of protection.

CANADIAN COURT TO INVESTIGATE A NOSTRUM.

An opportunity is now afforded in British Columbia to secure some light on the alleged harmlessness of "Chamberlain's Colic, Cholera and Diarrhea Remedy." We referred last week to the coroner's verdict on the death of an infant said to have been caused by this nostrum. The *Vancouver World* used some strong language in commenting on the case, and that paper is now sued for libel. We are glad to note that the *World* declares its satisfaction over the prospect. Some of these nostrums are being hard pressed by the exposures that are made, and they will, of course, fight back. Whether they will carry the fight actually into the courts remains to be seen; it is easy to commence a suit, and it has the effect of scaring the weak-kneed. But sometimes the courts get to bottom facts and find out the truth which some nostrum vendors are not anxious to have made known.

ONE ILLUSTRATION OF FRATERNITY AND CO-OPERATION.

An Idaho physician¹ who made application for license to practice was rejected because the results of his examination were not satisfactory, and the district judge to whom his appeal was taken reviewed his examination papers, raising the grade, but not raising it enough to pass him. He then appealed to the Supreme Court, and, while the case was pending, Dr. R. L. Nourse, the president of the Idaho State Medical Society, who was also a member of the State Board of Medical Examiners at the time the application referred to was acted on, commented rather pointedly, in his annual address, on the actions and words of this district judge. Besides quoting freely from the judge's opinion as handed down, Dr. Nourse said: "Think of it! A judge, however learned he may be in matters of law, sitting as superior to a board of six medical men on matters pertaining to medicine, gravely scrutinizing the markings given by a medical board to a candidate for a license to practice medicine, to see if he had been rated correctly. It would be intensely funny if it were not, in fact, so serious a matter." Further, commenting on the remarks of the judge concerning the subject of pathology, Dr. Nourse said: "It will, no doubt, be news to you that pathology is a subject that only specialists (he does not say what specialists) are expected to be posted on. Although every *bona fide* medical school in existence teaches pathology, and every state examining board must examine on it, yet this learned judge sweeps it aside as an unfair test." For these remarks Dr. Nourse was summoned before the judge, who fined him \$300.00

1 See Idaho news, this issue.

and costs for contempt of court. An appeal was taken to the Supreme Court, but it refused to set aside the action of the district judge and the fine was paid. Dr. Nourse's public criticism of the judge while the case was yet unfinished may have been technically wrong, but it was worth the fine to have the opportunity of expressing the frank opinion. The best part of the whole matter, however, is that the members of the Idaho State Medical Society showed their fraternal feelings in a practical manner by voluntarily taking such action that Dr. Nourse will be nearly, if not fully, repaid. They have paid to the secretary \$240.00, and more is still coming in. It is this spirit, which is the natural result of organization, that is so encouraging for the future, for it is a spirit that is gradually coming to prevail among the members of the profession in every state.

CONTAMINATED FOOD.

The work of securing pure food involves more than making laws against adulteration. Food which is not adulterated may yet be contaminated in its manufacture and preparation for market. In a recent article Mary Sherman,¹ of the National Consumers' League, portrays some conditions that almost make one afraid to eat. The article is illustrated and shows in what vile and disgusting quarters macaroni, ice cream, candy and other products are prepared. For the most part, these supplies are for consumption among the poorer classes, and the personal danger is not very apparent to the average person outside of the slums; but this can not be said of a New York nut factory, in which nuts are shelled for candy factories, bakeries and retail groceries. The firm makes a specialty of "health food" preparations, including nut marmalade, nut butter and nuts packed in glass jars. These products are sold in the best shops and are purchased by well-to-do people. The workers are described as being, without exception, dirty. Their hands were filthy. One girl, who separated the unbroken shelled nuts with her fingers, had ulcers on the backs of her hands. During the rush season the workers, who are largely Italians on poor wages, take work home. Some of these homes are said to be indescribably filthy and crowded. In one case, nuts were picked over by an Italian and his children. The father and one boy were tuberculous. The father had tuberculous joints, and during the time that he was engaged in this work he had had a knee-cap and part of the arm bones removed. The nut meats picked over in such houses by such persons lie on their tables over night and, on being returned to the factory, are not washed or cleaned, but are packed into jars to be sold at 25 cents each, with advertisements calling attention to the purity and cleanliness of the goods. These specific instances are simply cited to indicate the need of health inspection of the tenements; the pure-food agitation involves an immense amount of work and demands the sympathy of people in every walk of life, for self-protection as well as for the protection of those who have to buy cheap foods.

THE DIAGNOSIS OF INCIPIENT TUBERCULOSIS.

There is no subject which so imperatively requires the attention of the general practitioner as the diagnosis of incipient tuberculosis. It is generally admitted to-day that, if the symptomatology be recognized early enough, the sufferer in most cases can be restored to health. Yet the pathetic fact remains that the disease is generally not recognized until it has passed the incipient stage. The committee on nomenclature of the National Association for the Study and Prevention of Tuberculosis has provided this definition of incipency: "Slight initial lesion in the form of infiltration limited to the apex or to a small part of one lobe; no tuberculous complications; slight or no constitutional symptoms (particularly including gastric or intestinal disturbances or rapid loss of weight); slight or no elevation of temperature or acceleration of pulse at any time during the twenty-four hours, especially after rest; expectoration usually small in amount or absent; tubercle bacilli may be present or absent." Since most patients first consult the family physician, he ought to be a specialist in tuberculosis, and if a practitioner who assumes the important rôle of family physician does not feel proficient he should realize his responsibility and take steps to render himself thoroughly familiar with the symptomatology, diagnosis and treatment of this disease. In few other diseases will good and timely action bear so much beneficent fruit. In no other disease will the mournful results of unskillfulness and conscienceless neglect be visited so disastrously on the physician. It is not intended to set forth here the many factors to be considered. We would but emphasize the fact that conclusions must be reached only after the consideration of many details.¹ One among these would mean nothing; several taken together would be suggestive; a number combined would be conclusive. There is no telling to what a slight hint may lead. The faculty of judgment, of basing correct conclusions after having grasped essential features, the discriminative temperament, the scent for diagnosis, must here be called into play; and when it exists the physician can and will, without doubt, diagnose most cases of tuberculosis while the disease is in its incipency.

Medical News

IDAHO.

New Hospitals.—Articles have been filed for the incorporation of the Pocatello General Hospital with a capitalization of \$25,000, of which \$5,000 has already been subscribed.—Coeur d'Alene Hospital has been reorganized and incorporated by Drs. B. J. Seadon and W. W. Wood of Coeur d'Alene, and Drs. J. L. McGee and C. W. Crink, Wallace.—The Idaho Falls Hospital Association has been incorporated with a capital stock of \$20,000.

State Board of Examiners Has Quasi Judicial Powers.—A very important decision was recently handed down by the Supreme Court of Idaho bearing on the judicial powers of the State Board of Medical Examiners. Dr. Raaf took the examination for license to practice at the regular meeting of the

1. Report of the Committee on Early Diagnosis of the National Association for the Study and Prevention of Tuberculosis. THE JOURNAL, A. M. A., May 27 and June 3, 1905, pages 1706 and 1801. See also: "The Early Diagnosis of Incipient Tuberculosis," a circular issued by the Illinois State Board of Health, which can be obtained, we believe, by addressing Dr. James A. Egan, Springfield, Ill.

board in October, 1904, but failed, securing a general average of only about 56. Appeal was taken by him to the District Court, on a writ of review, and the judge was asked to re-rate the examination papers, which the judge did, and as a result raised the doctor's grade from 56+ to 69. And further, the judge in his findings says: "But I find pathology to be a subject that only specialists are expected to be conversant with, and I therefore set aside the subject of pathology entirely, and on all the other branches I find the plaintiff entitled to 73.48." This, however, was not enough to pass the plaintiff (the law requires 75), and the judge refused to order the board to grant him a license to practice. From this decision the plaintiff appealed to the Supreme Court, and recently this court handed down a decision wherein the board was sustained in its contentions that the district judge exceeded his jurisdiction in presuming to review and remark the examination papers of applicant for license, and that appeal from the decision of the board of examiners as to an applicant's fitness to practice medicine could only be taken on points of law. In other words, the board of medical examiners is given quasi-judicial powers, and so long as its actions are within and according to law, its decision as to an applicant's qualifications to practice medicine is final and without appeal.

ILLINOIS.

Illegal Practitioner Fined.—Stephen Picard was found guilty February 16 of advertising himself as a licensed physician, and was fined \$100 and costs.

State Charities Board Election.—The State Board of Charities met in the office of the secretary, at Springfield, February 13, and elected Dr. Frank Billings president.

Personal.—Dr. Francis E. North, Taylorville, was recently operated on for appendicitis in St. Louis.—Dr. Ezra Weiss, Peoria, is critically ill with cerebral hemorrhage.

Dedicate New Building.—The Illinois Western Hospital for the Insane, Watertown, dedicated its new amusement hall and two cottages for the treatment of insane consumptives, February 12.

New Hospital for Consumptives.—The building committee of the Cook County Board has approved the plan for the proposed emergency hospital for consumptives on the County Hospital ground, to cost \$15,000.

Civil Service Examination for Internes. The Civil Service Commission announced the following appointments for members of the examining board to conduct the examinations for internes for Cook County Hospital, March 6 to 10: Drs. Ferdinand Henofin, Charles S. Bacon, J. B. Colwell, Malcolm L. Harris, Charles E. Kahlke, John D. Robertson and Robert B. Preble.

Dr. McCormack's Visit. Dr. H. C. Mitchell, president of the Illinois State Medical Society, announces that Dr. J. N. McCormack will devote the entire month of April to Illinois. He will begin his itinerary in the ninth judicial council district, which is located in the extreme southern end of the state, and will take the districts according to their geographical arrangement, going from south to north. In the work of medical organization, says Dr. Mitchell, Dr. McCormack has no superior in the United States. The work he is doing is of the highest order and includes not only the medical profession, but the laity as well. There is a great demand for this kind of work throughout the entire country, because it brings the profession into closer and more harmonious relations, and teaches the physician his duty to his patient, and the patient his duty to his physician. Dr. McCormack invites the general public to all these meetings, and wants all classes of thinking people, such as lawyers, doctors, ministers, farmers, laborers, women's clubs, temperance organizations, county officials, congressmen, legislators and United States senators. Dr. McCormack says that often after he has delivered his lecture the physicians in attendance will say that it is too bad that the general public could not have been invited, as if it would have been just as intrusive to them. Dr. Mitchell, therefore, hopes that this mistake will not be made this time, as Dr. McCormack will only visit Illinois once, and, if the general public is not invited, it will be too late to rectify the mistake.

Chicago.

A Low Death Rate. For the week ended February 17, 527 deaths were reported, equivalent to an annual death rate of 13.41 per 1,000, which compares favorably with the rate of 13.34 for the previous week and with 16.50 for the corresponding week of 1905. Pneumonia led death causes with 80, fol-

lowed by consumption with 72, heart diseases with 49, violence with 37, Bright's disease with 29, acute intestinal diseases with 29, nervous diseases with 26, and cancer with 23.

Practical Disinfection.—The State Board of Health has issued a circular detailing the experimental work in formaldehyde disinfection done in its laboratory. As a result the board now feels justified in recommending formaldehyde for use in disinfection after contagious diseases, if employed by the methods described, with potassium permanganate and with 40 per cent. aqueous solution of formaldehyde, and believes that in properly sealed rooms positive and reliable disinfections can be secured by the use of 3½ ounces of potassium permanganate and one pint of formaldehyde solution to each 1,000 cubic feet of air space.

Dinner to Dr. Doherty.—Seventy-five members of the Chicago Medical Society attended a dinner in honor of Dr. David J. Doherty, February 17, at which Dr. Charles S. Bacon presided as toastmaster, and addresses were made by Drs. Scam, Evans and Corwin, eulogizing the thorough, able and conservative work of Dr. Doherty as a trustee and as a member of the society, and wishing him success in his trip to the Philippine Islands. Dr. Doherty responded, giving details of his plans of completing the dictionary of the Philippine dialects and stating that he expected to spend a year or two in sociologic and ethnologic studies before returning. A beautifully bound book, containing an address signed by all those present, was presented to Dr. Doherty.

MARYLAND.

To Prepare for Centenary.—A meeting of the alumni of the University of Maryland was held February 21 to prepare for the celebration in May, 1907, of the one hundredth anniversary of the medical department.

Personal.—Dr. Louis A. Griffith, Upper Marlboro, has been appointed a member of the State Board of Health.—Dr. Robert S. Tyson, Frederick, has been appointed physician to Montvue Hospital, Frederick County.—Dr. William B. Morrison, Hagerstown, has been appointed physician to Bellevue Asylum.

For State Sanatorium.—A bill has been introduced into the legislature appropriating \$25,000 for a state sanatorium for consumptives in the Blue Ridge Mountains. This sum will be devoted principally to the purchase of land, and the institution will be operated in conjunction with the hospital for consumptives in the suburbs of Baltimore.

Hospital Report.—The seventh annual report of the Cambridge Hospital shows that during 1905 777 patients were treated, with 24 deaths. The receipts and expenditures were each about \$12,550, leaving a small balance in bank. A special gift of \$800 was received for the purchase of a set of sterilizers and through private subscriptions an x-ray department, a bacteriologic laboratory and an operating room were equipped.

Lectures on Milk.—The State Board of Health inaugurated a course of lectures on milk February 20, to continue every Tuesday evening until May 1. The lectures are delivered in McCoy's Hall, Johns Hopkins University, and include the economic, dietetic and hygienic relations of milk, and will mark the progress of an exhaustive investigation covering the production, transportation, reservation, distribution, domestic care, dietetic uses, adulteration, sophistication, epidemiology and governmental control of milk and milk products of the country. The lectures will be followed by an exhibition under the auspices of the State Board of Health, the State Live Stock Sanitary Board, the Agricultural College of Experiment Station, and the Association for the Prevention and Relief of Tuberculosis.

Baltimore.

Health Report.—The health department estimates that there are at present more than 10,000 cases of influenza. During the week ended February 17, 49 deaths from pneumonia and 4 cases of smallpox were reported.

Personal.—Dr. John Turner was presented with a solid silver wine tray by a number of physicians in New York, who have united for original anatomic research.—Dr. George Wegelarth has gone to St. Augustine, Fla.

The Sale of Patent Medicines.—Dr. G. Milton Lithicum addressed the Armistice Club, February 15, in behalf of the bill now before the legislature regulating the sale of patent medicines, and on February 17 a public meeting was held at Johns Hopkins University in the interest of the same bill, over which Dr. W. S. Thayer presided.

Hospital Report.—Johns Hopkins Hospital reports that for the year ended January 31 there were treated 3,027 whites and 1,197 colored patients; of these 3,350 were discharged as well or improved, 130 as unimproved, 292 were not treated, 134 were transferred to other departments, and 243 died. In the dispensary 71,435 were treated.

MASSACHUSETTS.

New Hospital Dedicated.—St. Ann's Hospital, Fall River, was dedicated with elaborate ceremonies February 4 by the Rt. Rev. Bishop Stang. At present the institution can accommodate 87 patients.

Testimonial to Bowditch.—Over 400 patients who have been or are being treated at the Rutland Sanatorium presented recently to Dr. Vincent Y. Bowditch, who has been visiting physician there, a beautifully bound and illuminated testimonial in token of their regard for him.

Legacies.—By the will of Jasper P. Pope, Beverly, \$1,000 is bequeathed to the Beverly Hospital.—By the will of Mrs. Helen G. Cohnn the Children's Hospital, Boston, receives \$50,000 and the Cohnn fund of the Massachusetts General Hospital \$75,000.—Harvard College will receive a legacy of \$50,000 for its medical department under the will of the late George S. Hyde, to be paid on the death of Elkin P. Hyde and Mrs. Annie M. Sargent, brother and sister of the testator.

The Association Meeting.—The meetings of the American Medical Association, June 5 to 8, in Boston, come the week before the regular annual meetings of the Massachusetts Medical Society. The committee of arrangements for the latter has, therefore, decided to omit the scientific papers usually read before the medical and surgical sections on Tuesday afternoon. The time will be devoted to hospital visitation. All the other sessions of the state society will be held as usual, including the Shattuck lecture, on Tuesday evening.

Personal.—Dr. William P. Lawler, Lowell, has been made a member of the local board of health.—Mrs. Daniel S. Harkins an ex-Francis X. Crawford have succeeded Dr. Alfred A. Wheeler as physicians for the Boston street department.—Dr. Mary T. Bissell, New York City, has been elected superintendent of the North Adams Hospital.—Dr. Joseph N. Boyer, Jr., has been appointed city physician of Springfield, vice Dr. Simon J. Russell.—Dr. Joseph C. Pothier has been appointed medical inspector; Dr. Frank E. Stetson, chairman; Dr. Manuel V. Sylvia, quarantine physician, and Dr. Charles F. Connor, bacteriologist of the new Bedford board of health.—Dr. Carl H. Eidam has been chosen as chairman of the Lawrence board of health.—Dr. George A. Fagan has been appointed chairman of the North Adams board of health.

Change in Harvard Faculty.—The newly issued catalogue of Harvard Medical School shows 141 names in the list of faculty and instructors, one to every two students. A good many changes are to be noted. Those who have died or resigned are: Edward S. Woods, professor of chemistry; Francis H. Davenport, assistant professor of gynecology; H. H. A. Beach, John W. Elliot and John C. Munro, lecturers in surgery; Charles F. Withington, instructor in medicine; James O. Jordan, assistant in materia medica; James G. Mumford, instructor in surgery; and Drs. Samuel S. Maxwell, William A. Brooks, Jr., Hibbert W. Hill, George B. Magrath, Robert L. Emerson, David H. Walker, Clarence W. Keene. New appointees or promotions are: Drs. Louis Nelson, John W. Bartol, Robert B. Crenough, Ralph S. Lillie, Alexander Quackenbush, Eugene A. Crockett, Harvey P. Towle, Frederick S. Burns, Elliott P. Joslin, Harry C. Low, Arthur M. Worthington, George L. Baker, Francis W. Palfrey, Walter A. LeCompte, E. deW. Wales, Henry A. Christian, Carl L. Alsberg, Horace Bisney, Walter R. Brinkerhoff, Frederick E. Lord, Lawrence J. Henderson, S. Eurt Wolbach, George H. Wright, New Austin teaching fellows are: Dr. Fred T. Murphy, Dr. William L. Holt, and Dr. Fred W. Thyng.

Boston.

McLeod Guilty.—At a meeting of the board of trial of the Massachusetts Medical Society, held January 31, Dr. Percy D. McLeod was found guilty of unprofessional conduct. The penalty for this offense is expulsion from the society.

Staff Changes.—The following changes have been made in the visiting staff of the Boston City Hospital: Dr. Abner Post has resigned as senior visiting surgeon; Dr. Frank W. Draper as medicolegal pathologist, and Dr. Edward T. Twichell as physician to the Convalescents' Home. Dr. Herbert L. Burrell has been promoted to senior visiting surgeon; Dr. George H. Monks to junior visiting surgeon; Dr. Fred B.

Land becomes first assistant visiting surgeon; Dr. Frederick J. Cotton, second assistant visiting surgeon, and Dr. David Cheever, third assistant visiting surgeon. Dr. William H. Roby, Jr., has been appointed medical registrar vice Dr. John N. Coolidge, resigned.

MICHIGAN.

New Hospital.—The new Sault Ste. Marie Hospital was formally opened February 1.

Fire in Hospital.—The interior of the Michigan Children's Home Hospital, St. Joseph, was damaged by fire and water February 2 to the extent of \$2,500.

Change of Name.—Dr. Charles B. Nauerode, Ann Arbor, has had a petition granted by the judge of the Probate Court to change his name to Charles Bayard Guerdan De Nauerode.

Medicine Sample Distributor Convicted.—In the case of the Detroit Board of Health against Andrew McIntyre, charged with distributing samples of medicine from house to house in violation of the ordinance, the defendant pleaded guilty and threw himself on the mercy of the court and was released on suspended sentence.

Birth Registration.—The total number of births reported to the Department of State during January was 4,032, equivalent to an annual birth rate of 18.4 per 1,000. The registration for the first month of the operation of the new law requiring immediate registration of births has been satisfactory, although several districts made no report for the month. The number reported for the month, however, exceeds that for January, 1905, under the old law, by 830.

Academy of Medicine Election.—At the annual meeting of the Academy of Medicine of Southwestern Michigan, Kalamazoo, January 23, the following officers were elected: Dr. Alvin H. Rockwell, Kalamazoo, president; Drs. Norris A. Williams, Bangor, and Orin F. Burroughs, Plainwell, vice presidents; Dr. Walter B. Blayker, Kalamazoo, secretary and treasurer; Dr. Edward H. Van Densen, Kalamazoo, librarian, and Drs. George D. Carnes, South Haven, and Orton H. Clark, Kalamazoo, directors.

January Mortality.—The total number of deaths during January was 2,968, equivalent to an annual death rate of 13.6 per 1,000, as compared with 12.4 for December. Of the deaths recorded 544 were infants under one year of age and 943 of individuals aged 65 years and over. Among the important causes of death were: Pneumonia, 288; tuberculosis, 233; accidents and violence, 150; cancer, 135; diphtheria, 63; typhoid fever, 46; diarrheal and diseases of infants, 44; influenza, 39; whooping cough, 27; measles, 19; and scarlet fever, 18.

Personal.—Dr. A. S. Kitchen, North Escanaba, has been appointed local surgeon for the Chicago, Milwaukee and St. Paul Railway.—Drs. John Van der Laan and Frank W. Garber, Muskegon, have resigned as trustees of the Hackley Hospital in that city.—Dr. Roger S. Morris, Ann Arbor, instructor in internal medicine and demonstrator of clinical medicine in the medical department of the university, has accepted an appointment in the Johns Hopkins Hospital, Baltimore.—Dr. and Mrs. R. Adlington Newman, Detroit, sailed for the Mediterranean January 26.

MINNESOTA.

New Hospitals.—The George B. Wright Memorial Hospital, Fergus Falls, was opened to the public January 1. It has an accommodation for about twenty-five patients.—The German Lutherans of Mankato have decided to erect a hospital, to cost \$50,000, and with accommodation at present for forty-five patients.—A site has been donated for the Norwegian Hospital, Minneapolis.—The buildings are expected to cost about \$100,000.—The St. Paul Commercial Club has decided to erect a public hospital in that city to cost \$14,000.—Bethesda Hospital is to be erected in Crookston, as the \$12,000 fund required has been subscribed.

Personal.—Dr. Justus Ohage and family, Minneapolis, sailed for Naples from New York, February 24.—Dr. Andrew J. Gilkinson, Osakis, has been appointed a member of the State Board of Health.—Dr. Julian A. Du Bois, Sank Center, has been appointed a member of the board of managers of the School for Deaf and Blind, Faribault.—Dr. Frank Murphy, Caledonia, has been appointed physician of Houston County.

—Dr. Otto C. Quitman, Parker's Prairie, has been appointed local surgeon for the "Soo" System.—Dr. Charles W. More, Eveleth, has been reappointed a member of the State Board of Health.—Dr. Edmund W. Bayley, Sleepy Eye, has been ap-

pointed brigade surgeon, Minnesota National Guard, with rank of major.—Dr. J. V. Johnson has been appointed health commissioner of Eveleth.—Dr. and Mrs. Samuel D. Flagg, St. Paul, have gone to the Mediterranean.—Dr. Eduard Boeckman, St. Paul, has gone abroad.—Dr. Charles Freeman, St. Paul, has been elected secretary and treasurer of the Anglo-American Club of Berlin.—Dr. Christopher J. Woolway, St. Paul, has been appointed chief physician for the Delaware Mine in Keweenaw County.

NEW JERSEY.

Hospital Changes Name.—Bishop O'Connor and the trustees of the new Roman Catholic hospital, Orange, have decided to change its name from the Hospital of the Immaculate Conception to St. Mary's Hospital.

Recovers Damages.—The suit of Dr. Reginald S. Bennett, Asbury Park, to recover \$20,000 damages from Adolph Busch, St. Louis, whose automobile ran down the physician and his wife and child in June last, was decided February 7, and a verdict of \$12,292 was given the plaintiff.

Personal.—When Dr. Charles Brewer completed his duties as house physician in the New Jersey state prison, the officers of the prison presented a silver tea service to him. Dr. Brewer was house surgeon for fourteen years. He is succeeded by Dr. S. F. Stanger, formerly president of the board of prison inspectors.

Funds for Hospitals.—William T. Evans, the artist, has donated \$20,000 to Mountainside Hospital, Montclair, for the erection of a home for nurses. Miss Margaret S. Jarvis has also made a donation of \$5,000 to the institution.—Mrs. Everett Colby has sent \$7,000 to the New Jersey Orthopedic Hospital and Dispensary, Orange.

Contagious Disease in Camden.—The secretary of the board of health reported the number of cases of contagious diseases for the past month to be 71. Of these reported only two were of typhoid fever. This demonstrates the value of Camden's water supply, there having been practically no cases of typhoid fever since the installation of the artesian wells in this city.

Personal.—Dr. J. Walter Stiles, Jr., assistant physician at the Essex County Hospital for the Insane, Newark, was operated on for appendicitis, January 31.—Dr. William F. Ridgeway has been appointed city physician of Atlantic City, vice Dr. Leon H. Armstrong.—Dr. Charles C. Phillips, Deerfield, who has been a practitioner for fifty-two years in that place, expects to move to Pitman Grove.—Dr. and Mrs. C. D. Martinetti, Orange, returned from Europe by the *Princess Irene* January 25.—Dr. Joseph B. Shaw, Trenton, was thrown from his automobile and seriously injured, January 25.

NEW YORK.

Appeal for Stony Wold.—In order that this institution may claim the conditional gift of \$13,500, \$1,926 must be secured by March 1. The directors have been successful in raising \$17,575 and are making a great effort to get the balance required.

Work on State Hospitals.—The State Lunacy Commission has awarded contracts for work to be done on the state hospitals at Rochester, Poughkeepsie and Willard. At Rochester the north building of the hospital group is to be remodeled. At the Hudson River State Hospital a refrigerating apparatus is to be installed at a cost of \$7,395. At Willard a contract was let for the construction of a new cold storage building to cost \$10,131, and the installation of refrigerating machinery at a cost of \$7,163.

State Board of Charities.—Some of the recommendations for legislation contained in the recent report of this body are: That the appropriations to the state institutions be subdivided in the appropriation bill so that fixed sums shall be appropriated for food supply and clothing apart from the appropriations for salaries and other fixed charges; that the Craig Colony for Epileptics be enlarged as rapidly as possible, that it may be able to take epileptics of all classes from almshouses and other places where they can not receive proper care.

Against Consumption Colony. A bill has been introduced to prevent New York City from establishing a consumptive colony in Richmond for which appropriations have already been made. The bill seeks to make an amendment to the New York City charter giving local boards of improvement the power to recommend the establishment of penal institutions and hospitals within their districts, and further making provision that no such institution or hospital shall be established in any borough, if such local board, by vote of three-fourths of its members, disapproves.

State Health Report.—Dr. Eugene Porter reports that during the past year 1,554 deaths from typhoid fever occurred in the state, and that it was no exaggeration to say that almost every one was caused by infected water. The efforts of the health departments to prevent pollution of public waters should be supplemented by legislation which will give it further control of potable waters of the state by providing that all plans for public water supplies be approved by the state commissioner of health, and also to secure inspection of proposed and existing sewer systems. Not only was it important that all sewer systems in the different towns and municipalities in the state be investigated, comparison made and examinations conducted, but it was equally important that every sewer system, sewage disposal plant, manufacturing establishment, every municipality and summer resort should be thoroughly examined at least once a year and a competent report made in every case. The registration of births was far from satisfactory. The most incomplete registration was shown in Troy and Albany, where a birth rate of but 10.1 per 1,000 as against a resident death rate of 16.7 was recorded. In Troy the birth rate was 11.8 and the death rate 19.1. It was doubtful whether one-half of the births occurring in these cities were reported. The registration of marriages was also unsatisfactory. For this he recommended that a marriage license be required from the county clerk of the county in which the contracting parties resided. The following cities reported fewer births than deaths: Albany, Troy, Binghamton, Cohoes, Corning, Fulton, Hudson, Ithaca, Middletown, Newburg, Oswego, Rensselaer, Rome and Watervliet. The vital statistics for the year showed 172,259 births, 137,816 deaths and 78,261 marriages as against 165,014 births, 141,263 deaths and 74,677 marriages in 1904. Based on the recent census population the birth rate is 21.3 per 1,000 and the death rate 17.

New York City.

Personal. Dr. John N. Drury of Bellevue Hospital has gone to his home in Lowell, Mass., to undergo treatment for blood poisoning. It is feared that he will lose his arm.

Harvey Society Lecture.—The tenth lecture in the Harvey Society course will be delivered at the New York Academy of Medicine by Prof. Charles S. Minot, February 24, on "The Nature and Cause of Old Age."

Low Death Rate.—At the annual meeting of the trustees of the Helweg Infant Asylum it was reported that the death rate of the institution for the past year was 1 per cent. It was thought that this was the lowest death rate in any children's institution in the United States.

Poor Food for Steerage Passengers.—The captain of the steamship *Enry* of the Austro-American Line has been arrested charged with providing unwholesome food for infants in the steerage. Several other captains of ships in the immigrant trade have also been arrested for failing to obey the statutes relating to accommodations for steerage passengers.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended February 10, 1,390 cases of measles with 49 deaths; 432 cases of diphtheria with 49 deaths; 349 cases of tuberculosis with 161 deaths; 215 cases of scarlet fever with 16 deaths; 34 cases of typhoid fever with 7 deaths; 20 cases of cerebrospinal meningitis with 17 deaths, and 151 cases of varicella—a total of 2,591 cases with 299 deaths.

Out-Door Pneumonia Treatment.—Preparations are being made to remodel additional parts of the roof of the Presbyterian Hospital for the open-air treatment of pneumonia. This treatment has proved so successful that it is hoped the increased facilities will be available before the end of the winter. At present only children can be treated this way, as adults can not conveniently be carried on the roof and consequently receive treatment in small rooms with windows open.

Wood Alcohol in Communion Wine.—Health Commissioner Darlington told the alderman's committee on salaries and officers that the adulteration of the food and drink sold in this city had become so general that it had spread to communion wines, some of which are alcoholic. He had the contents of a bottle labelled "communion wine" analyzed and found wood alcohol, hard ether and anilin coloring matter. Dr. Darlington has planned a crusade against adulterated foods and drinks on a small scale. To make a complete job he thinks would cost the city \$500,000 a year. He has asked for power to appoint a supervising chemist at \$1,800 a year. When samples are found containing substances injurious to health he proposes to prosecute the makers and sellers. The committee decided to report favorably on Dr. Darlington's application.

NORTH CAROLINA.

Personal.—Dr. George A. Coggeshall, Henderson, is critically ill with pneumonia.—Dr. Isaac W. Faison, Charlotte, who has been seriously ill, is reported to be improving.—The vacancy in the office of coroner of Buncombe County, caused by the recent death of Coroner Dr. W. E. Hemphill of Arden, has been filled by the election of Dr. E. R. Morris of Asheville.

To Keep Water Pure.—Superior Court Judge Ferguson has made permanent the injunction recently obtained by the city of Durham from emptying their sewage into Eno Creek, restraining them from emptying their sewage into Eno Creek. The company is further ordered to provide a suitable system of sewage disposal at once, the method to be subject to the court's order, to the approval of the State Board of Health. The result is complete victory for the city of Durham and her efficient health officer, Dr. T. A. Mann.

Test Compulsory Vaccination.—The right of the state to enforce vaccination of school children is again to be tested in the courts of this state in a case now being developed in Union County. The county superintendent of health, Dr. H. D. Stewart, Monroe, went to the school house to vaccinate Mr. H. G. Griffin and his pupils, as there had been cases of smallpox in the vicinity and a general vaccination had been ordered. Principal Morgan declined to be vaccinated himself or to allow the children to be, alleging that their parents had forbid it being done. At the trial the teacher held that as the parents had forbidden the vaccination, had he permitted its being done he would have been personally and legally liable to them for damages, while the health officer contended that he should not have resisted the order of the health board. The final decision (which was reserved until March 10), rests on the rules adopted by the county board of health, the code of North Carolina saying it is a misdemeanor to violate the laws as passed by a county board of health, or to obstruct its operation, but it seems the code has been the subject of revision and a copy of the revised code, which went into effect only a few days ago, was not in court, hence the reserving of the decision.

OHIO.

Hospital Closed. The Marion City and County Hospital was closed February 6.

Gifts for Hospital.—At the annual meeting of the trustees of Lakeside Hospital, Cleveland, gifts were announced aggregating \$300,000.

Pay Ward Reopened.—The board of public service has decided to reopen the pay ward of the Cincinnati Hospital, holding, however, the right to close it again if the hospital should become so overcrowded as to necessitate its use for public cases.

Fires.—The residence of Dr. Leonard E. Warren, Marietta, was damaged to the extent of about \$300 February 1 by an explosion of natural gas.—Longview Hospital was damaged to the extent of \$1,000 by a fire which started in the superintendent's departments, February 10.

Cuspidors in Street Cars.—The State Board of Health has adopted a rule requiring companies owning and operating steam and electric cars not confined wholly within one municipal locality to provide cuspidors, and declaring it dangerous to public health to spit on the wall or floors of any such cars.

Distillers Object.—As was to be expected, considerable opposition has developed as a result of Health Officer Allen's recommendation to the Cincinnati health board to prohibit the sale of distillery slop to dairymen. If Dr. Allen's recommendation is adopted it will mean a loss of thousands of dollars a year to the breweries and distilleries, which, of course, is nothing to the owners of this otherwise unmarketable article, they claiming probably that it is an extremely useful article of diet for the milch cow.

Personal. Dr. W. A. Dickey, Toledo, who was recently injured in a street-car accident, is convalescent.—Dr. Goodhue Kineon, Cincinnati, has been appointed assistant at the Ohio Hospital for Epileptics, Gallipolis.—Dr. Oscar W. Bonner has been reappointed health officer of Delaware.—Dr. Orlando T. Maynard, Elyria, sailed for England February 6.—Dr. Frank C. Reed and family, Akron, left for a Mediterranean trip February 6.—Dr. Harry D. Belt, Kenton, has been reappointed physician of Hardin County.—Dr. James G. Shirera has been appointed surgeon of the B. & O. System at Newark.—Dr. Charles A. L. Reed, Cincinnati, has been chosen president of the Smoke Abatement League.—Dr. James A. Leech, Columbus, has been appointed physician at the workhouse.—Dr. Paul D. Hale, Dayton, is convalescent after a severe attack of pneumonia.

Non-Political Management of Hospital. At the regular meeting of the Cincinnati Academy of Medicine, January 29, a resolution was adopted providing for a committee of five who were to devise some means by which it would be possible to take the department of health and the City Hospital out of the hands of the political party in power; in other words, to form a non-partisan board for the governing of these two important departments of the city service. As the law now stands these departments come under the management of the governing power of the city and can not be taken from them except by act of legislature. Theoretically, everyone is prepared to admit that it would be for the good of the city and for the best interests of the physicians if these two branches of city government were in charge of non-partisan boards, but whether the idea can be carried out at the present time is problematical.

PENNSYLVANIA.

Smallpox at Bryn Athyn.—Three cases of smallpox were reported in one home in Bryn Athyn during the past week. Dr. Fred Johnson, chief medical inspector of the state health board, has been detailed by the health commissioner, Dr. Dixon, to take charge of the situation. The village may be placed under state quarantine on account of the refusal of many of its residents to submit to vaccination.

Philadelphia.

Bequests.—The will of the late Araminta P. Banks bequeaths \$25,000 each to the Home for Consumption, the Sunday Breakfast Association, and the Midnight Mission.

Health Report.—The deaths reported from all causes during the week numbered 612. This is an increase of 28 over last week, and an increase of 13 over the corresponding week of last year. The principal causes of death were: Typhoid fever, 37; measles, 14; diphtheria, 16; meningitis, 4; consumption, 81; cancer, 18; apoplexy, 14; heart disease, 55; acute respiratory diseases, 120; enteritis, 28; cirrhosis of liver, 10; Bright's disease, 45; old age, 14; accidents, 14, and marasmus, 4. There were 544 cases of contagious disease reported, with 59 deaths, as compared with 530 cases and 44 deaths reported in the preceding week. There were 429 new cases of typhoid fever, 725 of measles, 160 of pneumonia, 152 of tuberculosis, 78 of diphtheria, 51 of chickenpox, 37 of scarlet fever, and 4 of meningitis.

WISCONSIN.

New Building for Hospital.—St. Mary's Hospital, Milwaukee, is to be torn down and a new building erected on its site to cost about \$200,000.

Medicine Peddler Found Guilty.—On February 6 S. R. King, a medicine peddler of Beloit, was found guilty of practicing medicine without a license, and fined \$50 and costs.

District Society Meeting.—At the meeting of the Eleventh District Medical Society, held recently in Ironwood, Dr. Matthew S. Hosmer, Ashland, was made president, and Dr. Charles D. Conkey, Superior, secretary-treasurer.

Personal.—Dr. George D. Ladd, Milwaukee, was stricken with cerebral hemorrhage while performing an operation at Milwaukee Hospital, January 29.—Dr. Thomas W. Nuzum, Brookhead, has gone to Europe.—Dr. Patrick H. McGovern, Milwaukee, has succeeded Dr. John R. Curves, Two Rivers, as a member of the State Board of Medical Examiners.—Dr. Henry J. Stalker, Kenosha, was taken seriously ill at a banquet in Racine, February 6.—Dr. Lawrence Mayer, Hudson, has been appointed a member of the State Board of Health.

Fox River Society Meeting.—The Fox River Valley Medical Society held its annual meeting and banquet at Green Bay, Wis., January 16. The following officers were elected for the ensuing year: President, Dr. Robert E. Minahan, Green Bay; vice-presidents, Drs. Walter R. Hicks, Menomonie, Mich., and Henry W. Abraham, Appleton, Wis.; secretary and treasurer, Dr. Chester M. Echols, Appleton, Wis., and censor, Dr. William E. Fairfield, Green Bay, Wis. The secretary was instructed to thank *Collier's Weekly* in behalf of the society for its vigorous campaign against injurious nostrums.

Anniversary Meeting. The Milwaukee Medical Society celebrated its twentieth anniversary by a banquet at the University Club, January 12. The toastmaster was Dr. Horace Manchester Brown. The regular toasts were responded to by Drs. Samuel W. French, W. L. Washburn, G. J. Kaunheimer, A. T. Holbrook and T. L. Harrington. The society has increased from eight to 150 members in twenty years; has a library, reading room, pathologic museum and assembly room on the third floor of the Goldsmith building; owns a library of 5,000 volumes, and subscribes to 100 periodicals annually. Meetings are held bi-monthly and are well attended.

GENERAL.

Warren Essay Prize.—The Warren triennial prize was founded by the late Dr. J. Mason Warren in memory of his father, and his will provides that the accumulated interest of the fund shall be awarded every three years to the best dissertation (if any is considered worthy), on some subject in physiology, surgery or pathology; the arbitrators being the physicians and surgeons of the Massachusetts General Hospital. The prize for 1907 will be \$500. Essays will be received until April 14, 1907. A high value will be placed on original work. Dr. Herbert B. Howard, resident physician, may be addressed for further particulars.

Army Medical Corps Examinations.—Preliminary examinations for appointment of assistant surgeons in the Army will be held on May 1 and July 31, 1906, at points to be hereafter designated. Full information concerning the examination can be procured on application to the Surgeon General, U. S. Army, Washington, D. C. The applicant must be a citizen of the United States, between 22 and 30 years of age, a graduate of a legally authorized medical school, of good moral character and habits, and with at least one year's hospital training or its equivalent in practice. Applications must be in possession of the surgeon general on or before April 1. There are at present twenty-five vacancies in the medical corps of the Army.

CANADA.

Tuberculosis in Toronto.—There were 271 deaths in Toronto from tuberculosis in 1905, a rate of 1.03 per thousand. During the year 39 patients were sent to the Gravenhurst sanitarium and 75 to the Toronto institution.

Fee Schedule for Life Insurance Examinations.—At the regular monthly session of the Medical Society of the County of Colchester, Nova Scotia, January 30, a resolution was carried unanimously, and signed and agreed to by all the medical practitioners in the county, making the minimum charge for medical examination for life insurance, including all fraternal societies, \$5.

Toronto Will Disinfect All Houses After Consumption. The local board of health of Toronto, at its meeting February 7, decided to instruct its medical health officer, that hereafter all houses and apartments which have been occupied by patients suffering from tuberculosis must be disinfected. As all death certificates go through the hands of the medical health officer, his inspectors will be instructed to perform this duty the same as in cases of diphtheria.

Ask Aid of Government to Entertain the British Medical Association.—Physicians of Toronto, representing the local branch of the British Medical Association, appeared February 7 before the premier and the provincial cabinet to ask for assistance in entertaining the association next August, \$7,500 being the amount requested. The dominion government has partially promised \$10,000, and the city of Toronto is expected to contribute \$5,000, according to the newspapers.

Toronto Branch Victorian Order of Nurses.—The seventh annual meeting of the Toronto branch of the Victorian Order of Nurses was held February 14. The official report showed that during 1905 the nurses in connection with the institution cared for 522 patients, necessitating 6,842 visits, 500 being night visits. Two hundred and seventy-four physicians now employ nurses of the Victorian order. Of the 522 patients, 119 fully recovered, 45 improved, 15 sent to various hospitals and 14 died.

Ontario to Have Better Health Laws. The Ontario medical health act is to be amended and consolidated at the present session of the Ontario legislature. The board of health has recommended the better enforcement of enactments regarding vaccination, the disinfection of railway cars, street cars and other vehicles, and that no municipality shall have power to adopt a water system unless sanctioned by the board of health of the province. More stringent legislation will also be sought relative to sewage disposal methods.

The Marriageable Age in Manitoba. The Medical Society of Winnipeg, Man., at the regular meeting February 3, passed the following resolution unanimously with regard to child marriage: "The members of the Winnipeg Medico-Chirurgical Association are of the opinion that the marriageable age for females should not be less than 16 years, owing to physical immaturity before that age, and the almost certain procreation of weaklings in a large number of cases; and we believe child marriage from a scientific and humane standpoint to be a great evil to the individual and to the state."

Hospital News.—By the will of the late Mrs. Agnes Elizabeth King of Montreal the Montreal General Hospital receives a bequest of \$100,000.—The trustees of the estate of the late Mr. George Gooderham of Toronto, who was for many years chairman of the board of trustees of the Toronto General Hospital, have contributed \$25,000 to that institution.—Mr. D. D. Mann of Toronto and Winnipeg has donated \$10,000 to the Toronto General Hospital.—There were 51 patients in residence in January at the Toronto Free Hospital for Consumptives, 38 of these being inmates on city orders from Toronto.—The old Vancouver (B. C.) General Hospital is likely to be used for housing the wards of the Children's Aid Society of that city.—The Vancouver (B. C.) hospital board is considering a memorial signed by 35 practitioners of that city, asking that staff appointments be made for five years. At present the staff consists of 12 physicians in ordinary attendance, 11 consultants and 2 ophthalmologists.—During the week ending February 10 the total number of patients treated in the Winnipeg General Hospital was 361, of whom 200 were men, 107 women and 54 children.—Fire caused \$10,000 damage to the Rockwood Provincial Hospital at Kingston, Ont., on the night of February 9.—One hundred and ninety patients were received during 1905 into the Protestant Hospital for the Insane at Verdun, P. Q., 49 per cent. of whom were persons born outside of Canada. The total number in the institution at the end of 1905 was 654—343 men and 311 women.

FOREIGN.

Plague in Japan.—Dr. Moore, of the Public Health and Marine-Hospital Service, reports that the plague situation in Japan seems to be ameliorating, though the disease has not yet been entirely suppressed.

Orthopedic Congress in Germany.—The German Society for Orthopedic Surgery holds its fifth annual congress April 3, 1906, at Berlin. Adolf Lorenz of Vienna will preside. Dr. Joachimsthal, Berlin W., Magdeburgstrasse 36, is the secretary.

Röntgen Congress in Germany.—The German Röntgen Society announces its second annual congress April 1-2, 1906, at Berlin, preceding the German Surgical Congress. The general secretary is Dr. M. Immelmann, Berlin W., 35, Lützowstrasse 72.

British Medical Association and Proprietary Preparations.—The *British Medical Journal* states that an advisory committee has been formed to assist the editor in deciding what proprietaries shall be noticed in the columns of the journal. The members of this committee are Drs. Cusny, Dunstan and Dawson Williams, and Mr. R. H. Kinsey. Dr. Dawson Williams is editor.

Plague in Persia.—It is reported that plague appeared in January in Seistan, on the border of Lake Naryzan, Persia. All precautions were immediately taken by the Persian authorities, acting in conjunction with the Russian and British consuls. A sanitary cordon was established, with a period of observation of five days, isolation of the sick, and preventive vaccination. There are European physicians in the epidemic area. At the time of the report, January 18, the disease had caused about 200 deaths.

Other Congresses in Germany in April.—The German Congress for Internal Medicine will be held at Munich, April 24-27, and the Congress for Experimental Psychology at Würzburg, April 18-21. Külpe of Würzburg is in charge of the arrangements for this latter congress, and will open the proceedings with an address on the "Present Status of Experimental Esthetics." Krüger will follow with an address on the "Relations Between Experimental Phonetics and Psychology"; Schumann on the "Psychology of Reading"; Sommer on "Psychiatry and Individual Psychology," and Weygandt on "Psychologic Examination of the Congenitally Mentally Defective."

Sanitation in City of Mexico.—The board of health of the City of Mexico has entered on its campaign against insanitary conditions. It will require householders to keep their premises clean and landlords to increase the supply of water in tenement houses. Bath houses will be built at all police stations and dirty members of the lower classes will be arrested on the streets and compelled to bathe. Persistent beggars will be banished from the city. The dirty clothing of the very poor will be burned and they will be provided with new raiment. The congested population in the tenements will be dispersed and inspectors of health boards will be invested with extraordinary powers. This sounds energetic.

The Anglo-American Medical Association. The English-speaking physicians residing in Mexico have organized an asso-

ciation for scientific annual reunions. The first was held at Torreon, January 24-26, with Dr. D. Robinson in the chair. Dr. W. W. Ashurst of Chihuahua is chairman of the section for general medicine. Among the subjects discussed were tropical fevers, neuroses, practice of obstetrics in Mexico, mercury cyanid in treatment of syphilis, etc. The *Escuela de Medicina* for January 31 gives the program in full of each of the four sections. Scientific communications were presented by twenty-three different physicians. Our exchange deplores the avowed determination of the founders to restrict the addresses and discussions to English.

Yellow Fever in Bocas del Toro.—It is reported that Bocas del Toro, off the coast of Colombia, is a yellow fever center and that the Public Health and Marine-Hospital Service has been requested to take charge of the island and clean it out. The party of southern health officers who are making a tour of inspection of Central American fruit ports, state that the conditions at Bocas were so deplorable that every member of the party realized that unless something was done immediately Bocas would not be given the least consideration by the health authorities of the southern ports, and would prove such a menace to the other Central American ports that it would interfere with the desire to preserve comparatively open communication with them. It is stated that there is no pretense of enforcing health regulations. A pernicious form of malaria is also prevalent. An examination of water tanks and barrels showed them to be swarming with the *stegomyia*.

Ramon y Cajal.—The Madrid Faculty of Medicine has recently published a list of the scientific works of Ramon y Cajal, its great histologist. Although only 54 years old, he has published 162 works, and has received the Fauvel prize, the Helmholtz medal and the prize given by the International Medical Congress at Moscow, and has been invited to deliver the Croonian and other important lectures in foreign lands. He is also honorary member of two dozen scientific societies outside of Spain. The *Siglo Medico* of Madrid comments with amazement on what this great scientist has accomplished alone, without means and without aid, almost forgotten by the immediate circle around him until reminded of his existence by the honors heaped on him from foreign countries. His father was professor of anatomy at Saragossa, and his own first official position was the chair of anatomy at Valencia. His works have mostly been published in book form, or in the *Revista Trimestral Micrografica*. He visited this country in 1899 to lecture on invitation at Clark University.

Plague and Smallpox in India.—It is reported that the plague mortality in India is gradually rising. During the first week in January the United Provinces reported the greatest number of deaths, about 1,100; Bengal followed with 1,000. In Bombay presidency there were only 800 deaths; in the Punjab, 500; in the Central provinces, 200, and in Burmah about 100. Sixty-one deaths from smallpox were reported in Calcutta during the first week in January, and it is probable that many more cases existed, not including concealed cases. The epidemic began in Watzunge, Kidderpore, but probably on account of the work of the vaccination department, which made over 3,000 vaccinations in that district during December, the disease has been practically mastered, and the returns there are about normal. Other districts and wards have been attacked, and the present outlook is certainly grave. All the vaccine stations, fifteen in number, are doing their utmost to vaccinate and to induce guardians and parents to permit their children to be vaccinated.

International Medical Congress. This congress at Lisbon bids fair to be one of unusual importance, although the number in attendance probably will be smaller than when it has been held in some of the larger capitals. Papers will be presented by some of the leading lights of the profession in Europe. The meetings will be held at the Medical School of Lisbon, which is a large building. Everything will be under one roof, and everyone will know where to find everything connected with the congress, as well as everything that is needed in a general way. There will be the office of the president, secretary and treasurer of the congress, telephone room, typewriting room, press room, information room, where one can find out all particulars regarding the various routes of travel; halls for showing different apparatus; amphitheatres for giving lantern exhibitions; a postoffice and telegraph office, registration room, money exchange, and a room where papers, cigars, cigarettes, etc., will be on sale. The opening exercises will be in the Geographical Society building, where a colonial exposition will take place during the meeting, under the auspices of the sections on colonial and naval medicine. Addresses will be delivered each afternoon at the general

meeting by distinguished representatives of different countries. Sir Patrick Manson will represent England; Prof. E. von Bergmann, Germany; Professor Reclus, Paris; Professor Neumann, Austria; Prof. Prince Jean Tarschanoff, Russia; Prof. Azevedo Sodre, Brazil; Dr. José Maria Esquerdo, Spain; Dr. P. Aaser, Norway. The names of those from other countries are not yet announced. Dr. Nicholas Senn of Chicago has been invited to deliver the oration for the United States. The amusements will include three large general fêtes, besides receptions and dinners. A large steamer will go from London and one from Hamburg, and these will serve as hotels during the stay there. One of the steamers can accommodate 300 passengers. The hotel and other accommodations are in the hands of Mr. Manuel José da Silva, Redaction do Annuario Commercial de Portugal, Praça dos Restauradores, Palacio Foz, Lisbon, to whom all communications concerning board and lodging in Lisbon should be addressed. All communications regarding the scientific part of the congress should be addressed to Dr. Ramon Ginteras, secretary American National Committee, 75 West Fifty-fifth Street, New York. All questions regarding transportation to Lisbon and return should be addressed to Dr. Charles Wood Fassett, St. Joseph, Mo. Arrangements are to be made by him in a few days for hotel accommodations in Lisbon for his party.

Pharmacology

THE GREAT AMERICAN FRAUD.

The Fundamental Fakes.

The sixth of Mr. Adams' contributions in *Collier's Weekly*, February 17, contains little that is new, but it emphasizes several important facts which have contributed to the financial success of a number of well-known patent medicines. Foremost among these stands advertising, both in the lay newspapers and in medical journals. Mr. Adams says that advertising and testimonials are respectively the aggressive and defensive forces of the Great American Fraud. Without the columns of the newspapers and magazines, wherein to exploit themselves, a great majority of the patent medicines would peacefully and blessedly fade out of existence. He has found that the strongholds of the fraud are the dailies, great and small, the cheap weeklies, and the religious press. Mr. Adams says that in one respect some of the medical journals are far below the average of the newspapers, and on a par with the worst of the religious journals. They offer their reading space for sale, and he reproduces a letter from a well known medical monthly making such an offer.

Mr. Adams is convinced of the gullibility of the American public as regards patent medicines. He speaks at length of the manner in which testimonials are obtained, often at great expense, from totally irresponsible persons. The geographical distribution of these endorsements is, he thinks, suggestive. Out of 100 specimens selected at random from the Pierce testimonial book, 87 are from small remote hamlets, whose very names are unfamiliar to the average man of intelligence. Only five are from cities of more than 50,000 inhabitants.

Mr. Adams' closing paragraph is significant, and portrays things as they are. He says: "Our national quality of commercial shrewdness fails us when we go into the open market to purchase relief from suffering. The average American, when he sets out to buy a horse or a box of cigars, is a model of caution. Show him testimonials from any number of prominent citizens, and he would simply scoff. He will, perhaps, take the word of his life-long friend, or of the pastor of his church, but only after mature thought fortified by personal investigation. Now observe the same citizen, seeking to buy the most precious of all possessions, sound health. Anybody's word is good enough for him here. An adulterer whose puerile vanity has betrayed him into a testimonial, an obliging and conscienceless senator, a grateful idiot from some remote hamlet, a renegade doctor, or a silly woman who gets a bonus of a dozen photographs for her letter—any of these are sufficient to lure the hopeful patient to the purchase. He wouldn't buy a second-hand bicycle on the affidavit of any of them; but he will give up his dollar and take his chances of poison on a mere newspaper statement which he doesn't even investigate. Every intelligent newspaper publisher knows that the testimonials which he publishes are as deceptive as the advertising claims are false. Yet he saves his conscience with the fallacy that the moral responsibility is on the advertiser and the testimonial giver. So it is; but the newspaper shares it.

When an aroused public sentiment shall make out public men ashamed to lend themselves to this charity, and shall enforce on the profession of journalism those standards of decency in the field of medical advertising which apply to other advertisers, the Proprietary Association of America will face a crisis more perilous than any threatened legislation. For printer's ink is the very life blood of the noxious trade. Take from the nostrum venders the means by which they influence the millions, and there will pass to the limbo of pricked bubbles a fraud whose flagrancy and impudence are of minor import compared to the cold-hearted greed with which it grinds out its profits from the sufferings of duped and eternally hopeful ignorance."

Mr. Adams also points out that as a convincing argument many nostrums guarantee, not a cure, as they would have the public believe, but a reimbursement if the medicine is unsatisfactory. Other concerns send their remedies free, on trial, and still others go so far as to offer a reward for proof that the stuff will not perform the wonders advertised. Mr. Adams says that if every subscriber to a newspaper who is interested in keeping his home free from contamination would protest and keep on protesting against advertising dishonesty of this nature, the medical advertisers would soon be restricted to the same limits of decency which other classes of merchandise accept as a matter of course, for the average newspaper publisher is sensitive to criticism from his readers. Furthermore, no perpetrator of unclean advertising can afford to go to court on the ground of breach of contract by the newspaper publisher, because his case is indefensible.

No Longer Members of the Proprietary Association.

The Horlick's Malted Milk Company, Racine, Wis., asks us to announce that the firm is no longer a member of the Proprietary Association of America.

Price of Phenacetin (Acetphenetidinum) to Be Reduced.

The patent on phenacetin expires on March 27, and after that date it will be sold at 33 cents in ounce lots. If bought or purchased under the pharmacopie name—acetphenetidinum—the price will be \$1.15 a pound or 7 cents an ounce.

Ayer's Cherry Pectoral.

BOSTON, MASS., Feb. 12, 1906.

To the Editor:—I have been interested in the formula of "Ayer's Cherry Pectoral" thus far submitted. Here is another from the note book of my father, Dr. J. L. Stevens, who many years ago practiced in Eastern Maine, and copied by him from Braithwaite's Retrospect in 1848:

R. Morph. acet.	gr. iv
Tb. saccharine	5ij
Vin. tart. antim.	
Vin. ipecac.	5iij
Syr. pum. virg.	5iij

C. B. STEVENS, M.D.

DULUTH, MINN., Feb. 15, 1906.

To the Editor: In Olsson's "Secret Nostrums and Lists of Medicines," published in 1891 in Chicago, is given the same formula of Ayer's Cherry Pectoral as given in THE JOURNAL, February 10, except that the earlier formula, taken from the *Pacific Medical and Surg. Journal*, contains gr. iij (instead of gr. iss) of morphin acetate in the three ounce mixture—double the amount of acetate morphin given out by the Ayer people.

HOMER COLLINS, M.D.

Leucoplasmia.—Lacapere (*Archives Gén. de Méd.*, 1905), does not believe that a non-syphilitic leucoplasmia exists. He thinks that two conditions are usually requisite for its appearance; first, the existence of persistent or recurring mucous patches; this is the primary cause; second, chronic inflammation at the locations of the ulcerations, due chiefly to irritation by the use of tobacco, alcohol, etc., and, secondarily to this, of the constant muscular movements of the parts. He does not say that this absolutely explains all cases. There may be possibly a leucoplasmia occurring without preceding mucous patches, but if such a condition exists it must account for only a small proportion of cases.

Medical Legislation

The Postoffice Attitude Toward Nostrums.

The chairman of the National Legislative Committee addressed the heads of the various departments of the national government requesting information relative to proposed medical legislation. These communications were sent in November under the impression that the meeting of the National Legislative Council would be held in December. Events, however, showed that it would be better to defer that conference until Jan. 9, 10 and 11, 1906, at which date it was held. All of the departments manifested their appreciation of the interest thus shown by the American Medical Association. One of the most appreciative letters and one dealing with exceedingly important subjects was from the postmaster-general, as follows:

OFFICE OF THE POSTMASTER-GENERAL.

WASHINGTON, D. C., Jan. 12, 1906.

Dr. Charles A. L. Reed, Chairman, Cincinnati:

My Dear Sir:—Apologies are due you for the delay in answering your communication of November 4, stating that a meeting of the Legislative Committee of the American Medical Association is to be held at Washington in December, and expressing the wish that you be advised of any legislation on medical subjects which may be desired by the Postoffice Department. This delay has been due to the desire to give full consideration to the question of the department's attitude regarding proposed legislation.

The Postoffice Department will recommend to Congress legislation authorizing the exclusion from the mails of all publications and circular matter promiscuously advertising or promoting the sale to the general public of remedies or appliances for the treatment of private or sexual diseases, or proffering to the public personal services in the treatment of such diseases, and making it an offense to deposit such matter in the mails; expressly providing, however, that circular matter advertising such remedies or appliances may be mailed to physicians and legitimate dealers, under cover of envelopes. This department has suppressed many concerns advertising and selling through the mails such remedies or appliances, on evidence that purchases of them were being induced by means of fraudulent representations. In other cases in which conclusive evidence of fraud could not be obtained, the advertising matter has been held to be indecent and its revision required. Other concerns carrying on similar enterprises, however, have so far succeeded in evading the law, and it seems impossible to reach and to suppress them without additional authority from Congress. It is believed that a statute making it an offense to deposit in the mails matter advertising any such remedy, appliance, or treatment, and authorizing its confiscation when found therein, would have a most wholesome moral effect, as well as afford needed protection to credulous and unfortunate persons.

Section 3893 of the Revised Statutes, as amended by the act of Sept. 26, 1888 (1 Supp. R. S. 621), provides for the punishment by fine and imprisonment of any person depositing or causing to be deposited in the mails any "article or thing designed or intended for the prevention of conception or procuring of abortion," or any "article or thing intended or adapted for any indecent or immoral use," or any "written or printed card, letter, circular, book, pamphlet, advertisement or notice of any kind giving information, directly or indirectly, where or how, or of whom or by what means" any of the articles or things enumerated may be obtained or made. The opinion has been expressed by the United States district attorneys that the sending through the mails of information indicating where abortions will be performed or can be obtained, whether in the form of a circular or newspaper advertisement, is not forbidden by this statute; and they have accordingly declined to institute criminal proceedings in such cases. These are frequently arising, and it is desirable that this defect in the statute be remedied by amendment.

It is believed that with these exceptions the existing laws afford as complete authority as the Post Office

Department can effectively exercise in the direction of purifying the mails and safeguarding the public from fraud and other imposition practiced in connection with the sale of medicines, appliances, etc.

This department will be pleased to receive and consider any suggestions offered by the American Medical Association in the matter of legislation along these general lines. Very truly, yours,

GEORGE B. CORTELYOU.

All of the foregoing letter following the first and preceding the last paragraph has been reduced to the form of a memorandum to which the Committee on Legislation has appended the following:

Resolved, By the American Medical Association that the recommendations of the Postmaster-General, contained in the foregoing memorandum be, and are hereby, approved, and that their enactment into a law is hereby respectfully urged on the Congress.

Physicians and Legislation.

In several states bills are now before the legislatures relating to the control of the "patent-medicine" and food-adulteration evils. The relation of physicians to the health problems of the community gives them vital interest in these bills, and, instead of contenting themselves with talking about the bills at medical societies and passing resolutions which are never heard of outside the medical profession, physicians should appear before the committees to which the bills are referred. More than any other persons, physicians have positive evidence to prove the fraudulent or dangerous character of most patent medicines. In commenting on this subject the *Maryland Medical Journal* says:

"Last winter a bill to regulate the 'patent-medicine' business was introduced in the legislature of Massachusetts. The advocates of the measure argued that its provisions were approved by a great weight of medical opinion, but this argument was disposed of easily and completely. The opposition said: 'There is no evidence whatever that this bill is supported by the medical profession. If physicians really favored the measure, they would do as other citizens do—appear before the committee and urge its passage. No physicians have appeared before the committee, and for us the proof is conclusive that the few lay people, who have appeared, represent the full strength of the proposition, and that the people of Massachusetts, including the physicians, do not want any such legislation.'"

Correspondence

Interstate Reciprocity.

DETROIT, Feb. 15, 1906.

To the Editor:—I have read with more than ordinary interest the article entitled "Inter-state Reciprocity," by Dr. George W. Webster, president of the Illinois State Board of Health and secretary of the Council on Medical Education of the American Medical Association, published in *THE JOURNAL* of February 10. Dr. Webster enumerates several of the fundamental facts entering into the question of interstate reciprocity. To nearly all of such facts quoted I can very heartily subscribe, namely:

First.—Medical education and the license and control of the practice of medicine is purely a state function.

Second.—The state medical board is the only body authorized by the state to determine the conditions and qualifications under which a medical license is granted.

Third.—Medical laws are enacted for the benefit of the people, rather than for the benefit or profit of the medical profession.

Fourth.—Each state has constitutionally established standards of its own, and such standards in consequence lack uniformity.

Fifth.—Each of the 157 medical colleges practically sets its own standard. (This is only true in a degree.)

Sixth.—Various associations of medical colleges and medical societies have established standards, but such standards are ineffective in law from want of authority of both associations and societies.

I have substituted medical societies for "medical boards" in Dr. Webster's text, as the latter could not have been meant and, therefore, is clearly an error, but Dr. Webster, in his enumeration of facts, has omitted at least two sets of facts which are not only fundamental ones, but which are most important from the standpoint of a practical solution of the difficulties met with in the administration of the several state reciprocity clauses, namely:

Seventh.—The great majority of states recognize, and, therefore, have legalized, three or more distinct schools of practice, no one school of which in law is less or greater than the other, and that in all questions involving standards, reciprocity and administration no one school, however preponderating its membership, has the authority to settle such a vital question as reciprocity without the co-operation and support of all the schools of practice recognized in the several states.

Eighth.—No proper or effective medical law has been enacted in any state except by and with the co-operation of the several schools of practice legalized in such states.

Dr. Webster, having omitted in his statement of facts a large percentage of the most material facts connected with and necessary to the success of inter-state reciprocity, it naturally follows that his suggestions for a solution of the difficulties met with in the question of inter-state indorsement of licenses, based entirely on his defective presentation of facts, must, therefore, be impractical and subject to criticism and deserved opposition, and can not possibly result in any good to the cause which he seemingly advocates.

His statement of facts under "Second," viz., that the state medical board is the only body authorized by the state to determine the condition and qualifications under which a medical license is granted, and his proposed remedy, namely, "Equal requirements, uniformity in entrance requirements, uniformity in length and character of the medical course, uniformity in the scope and character of the examinations, should be done through the organized profession, as embodied in the American Medical Association and by its Council on Medical Education," has only to be quoted to show absolutely the impracticability of his proposition. His proposed remedy is not only in direct conflict with his statement of facts under "Second," but also in direct conflict with the remaining divisions of facts, including "First" to "Eighth," inclusive. It is possible for Dr. Webster, or, for that matter, any one else, or any association of persons, except a state legislature, to confer on the Council of Medical Education of the American Medical Association, of which he is secretary, the authority which he truly states is solely vested in state medical boards?

The proper and equitable administration of the reciprocity clauses of the several states is a matter solely within the authority of the state medical boards interested. These medical boards are capable of fulfilling the duties and responsibilities with which they are charged by the state, and do not require unauthorized persons or associations to measure their authority or to perform their legal duties. The boards, however, are appreciative of intelligent assistance from associations in carrying out their difficult duties, provided there is no usurpation of the authority of the state responsible for their status.

I would very diffidently inform Dr. Webster, as he seemingly has forgotten the matter, that some four years ago a confederation of state medical boards was founded on the basis of the fundamental facts as subscribed by himself. This confederation, with a membership at present of nearly 50 per cent. of all the states, has succeeded in establishing practical medical reciprocity in some twenty-one of the better states, including Dr. Webster's own state, Illinois. It has also adopted an itemized standard of preliminary and medical education, which standard has also been adopted and is being enforced by the Association of American Medical Colleges. It has also, at the solicitation of Dr. Webster, adopted a "scope and character of examination." In the brief period of four years it has already more than fulfilled all the several divisions of basis for reciprocity advocated by Dr. Webster. No confederation or association ever founded in this or any other country has accomplished such a quality and quantity of practical work in so short a period, and while Dr. Webster seemingly

has overlooked the existence and deeds of the American Confederation of Reciprocating, Examining and Licensing Medical Boards, a lesser authority, perhaps, the Association of American Medical Colleges, gives it due praise and credit.

It may be of interest to the profession to know that this Association of American Medical Colleges and the American Confederation are working together harmoniously and practically along similar lines, having in view the unification of the standards of preliminary and medical education. I will prophesy that at the next meeting of the Association of American Medical Colleges, to be held at Pittsburg, March 19, 1906, its membership will be astounded at the amount of practical work accomplished since its last meeting, and also at the quality of such work.

I would suggest to Dr. Webster and to his committee the virtue of co-operation with the above association, in which much practical good along the lines of the committee's legitimate objects could be accomplished, as opposed to his entering a field entirely without the range of the committee's power and status.

B. D. HARRISON,
Secretary Michigan State Board of Registration in Medicine.

Johns Hopkins Course Not to be Lengthened.

BALTIMORE, Feb. 13, 1906.

To the Editor:—In your last issue I find a statement that I should be glad to have you correct. The statement is this:

"The authorities of the Johns Hopkins University are considering the question of lengthening the course in the collegiate department from three to four years, and that in the medical school from four to five years."

A committee is working on the problem of the college course, but what that committee will report I do not know. There is absolutely no foundation for the statement that the authorities of this university are considering the question of lengthening the course in the medical school from four to five years.

IRA REMSEN, President.

Prophylaxis of Venereal Diseases.

SEATTLE, WASH., Feb. 14, 1906.

To the Editor:—As chairman of the committee of venereal prophylaxis of the Washington State Medical Association, I desire to appeal to your readers to aid this committee in securing the names and addresses of physicians who would forward notice of any legislative action, state or municipal, or action taken by any society, corporation, or individual that would bear on this subject.

The object sought is to classify and to redistribute such literature in a condensed form and thus lead to a more uniform and concentrated action.

At the same time, we wish to compile a list of the physicians who desire to receive and to exchange literature, abstracts, papers, or reprints bearing on this subject and later, if possible, to establish a bureau of inquiry to which references may be made by any of those desiring knowledge on this subject.

Therefore, we should be very pleased to receive the names and addresses of any physicians who would like to take part in the work of advancing this branch of preventive medicine. Such a list would not be given publicly.

G. S. PETERLIN, M. D.

Prostitution.

LOS ANGELES, CAL., Feb. 17, 1906.

To the Editor:—Articles on such subjects as that discussed by Dr. Howard A. Kelly in THE JOURNAL, February 10, usually provoke prolific discussion. Medical men are generally aware of the futility of regulation. Such movements are usually promoted for the graft, for which they afford an unequal opportunity.

Dr. Kelly's suggested remedy is very discouraging, in view of the fact that this evil has attained its present magnitude in a nation of Puritan origin, in which human belief in divine intervention is widely prevalent. Dr. Kelly's deserved reputa-

tion as a surgeon is dependent on his knowledge of pure surgical science, divested of all dogmatic tradition. Religion is a large factor in the prevention of evil; publicity and public opprobrium is a still greater deterrent, but the Moses who will lead us out of the sexual wilderness must take his cue from Nature. Nature's method (and she will ultimately triumph) is to subdue sexual sins against society by causing sterility and death of the sinner. This is a slow process, but might be materially hastened by our co-operation.

When will mankind cease to overvalue the life of criminals, and to extend to them the privilege of reproducing their kind? The greatest obstacle to the accomplishment of these ends is dogma.

FRANK GORDON.

Psychopathic Manifestations of Non-Insane Psychoneuroses.

NEW YORK, Feb. 16, 1906.

To the Editor:—In a letter published in THE JOURNAL, Dec. 16, 1895, I said that the term "psychosomatosthenia," coined and introduced by Dr. John Puntin, belonged to what I am in the habit of calling "Lexicon-Greek." I also said that phrenosomatitis might express the same meaning, but that I would not dare to offer it for adoption before consulting Greek friends regarding its acceptability. I wrote to my esteemed friend Dr. B. Leonardos, the director of the Museum of Inscriptions in Athens, who is a physician and a philologist, and received the following information: "The word phrenosomatitis does not seem to me appropriate. Psychosomatosthenia is to be rejected. I believe that the disease can not be named with one word, and that even two words which will correspond exactly with the meaning can not easily be found."

A. ROSE, M.D.

A. W. Orriss Is Wanted.

ORIOLE, MD., Feb. 12, 1906.

To the Editor:—Any one having any information which will lead to the location of a man calling himself A. W. Orriss, M.D., will confer a favor on the members of the profession in Somerset County, Maryland, by communicating with the undersigned. This man represents himself to be the proprietor of a medical book store and calls on physicians offering to exchange new editions of medical works for the old editions in the physician's library. He exacts a payment from the physician "to cover freight charges and as an evidence of good faith," so he says, and departs, and this is the last any one sees of him. He operated in Somerset county to a very profitable advantage to himself and any information which would lead to his arrest would be greatly appreciated.

RALPH L. HOYT,

Secretary Somerset County Medical Society.

Marriages

EUGENE A. STURM, M.D., to Miss Mae Salb, both of Jasper, Ind., February 12.

H. J. H. HORVE, M.D., to Miss Pearl Brown, both of Des Moines, Iowa, February 2.

WILLIAM L. DENN, M.D., to Mrs. Gussie Bergman, both of Oakland, Cal., February 8.

ROBERT C. CHAMBERLAIN, M.D., to Miss Meta McCall, both of Tiffin, Ohio, February 15.

WILLIAM E. LUTER, M.D., to Miss Eleanor Maury, both of San Antonio, Texas, February 6.

HENRY LOUIS HAMMOND, M.D., Dayville, Conn., to Miss Cora Ward of Niles, Mich., February 6.

BENJAMIN VAN DORN HERRICK, M.D., Plainfield, N. J., to Miss Adele Cuts Williams of Chicago.

JOSEPH HAMILTON, M.D., Fruitvale, Cal., to Miss Jessie Aitken of Alameda, Cal., February 2.

BENJAMIN F. LEMMAN, M.D., Home City, Ohio, to Miss Edith Saylor of Cincinnati, February 20.

ALBERT W. SLAUGHTER, M.D., Paris, Ill., to Miss Mary Golden of Urbana, Ill., February 10.

STUART Z. PEOPLES, M.D., to Miss Helen Marie Anderson, both of Petahuma, Cal., February 4.

WILLIAM KEITH MITTENDORF, M.D., to Miss Marie Alvina Borchers, both of New York, February 15.

JOSEPH SPENCER DE JARRETTE, M.D., to Chestney Hopkins, M.D., both of Staunton, Va., February 14.

WLADISLAW A. KUFLEWSKI, M.D., Chicago, to Miss Angeline R. Cwiklinski of Buffalo, N. Y., February 21.

WILLIAM C. PETERS, M.D., to Miss Adah Bryant, both of Bangor, Maine, at Concord, Mass., February 1.

EBER D. MCKINLEY, M.D., Atlanta, Ind., to Miss Effie L. Howard of Athens, Ohio, at Indianapolis, February 7.

RAYMOND DEAN TOMPKINS, M.D., Jasper, Fla., to Miss Eliza Beth Wisling Massey of Philadelphia, February 21.

MAJOR FREDERICK P. REYNOLDS, M.D., U. S. Army, to Miss Hortense Cedilia Child of Los Angeles, Cal., February 21.

JEHIEL WESTON CHAMBERLIN, M.D., St. Paul, Minn., to Mrs. Jane Huntington Yale of Minneapolis, Minn., February 15.

JOHN P. REIMOND, M.D., Dysart, Iowa, to Miss Freda C. Schley of Iowa City, Iowa, at Cedar Rapids, Iowa, February 7.

Deaths

Newell E. Landon, M.D. College of Physicians and Surgeons in the City of New York, 1876; a member of the American Medical Association, New York State Medical Association, Central New York Medical Association, Wayne County Medical Association, and New York & New England Railway Surgeons' Association; surgeon for the New York Central, West Shore and Pennsylvania Railways; consulting physician to the State Custodial Asylum for Feeble-minded Women; three times president of the village of Newark, N. Y., and one of the most prominent physicians of Wayne County, died at his home in Newark, February 7, from cerebral hemorrhage, after an illness of two months, aged 52.

John Slade Ely, M.D. College of Physicians and Surgeons in the City of New York, 1886; assistant in pathology in his alma mater; professor of pathology in the Women's Medical College and later pathologist at the Bellevue Hospital; professor of theory and practice of medicine, Yale University Medical Department, New Haven, and one of the most brilliant members of that faculty; in 1896 president of the New York Pathological Society, died at his home in New Haven, February 7, from concussion of the brain, the result of an accident two days before, when he was thrown from his horse, sustaining a fracture of the skull, aged 45.

Francis Noel Burke, M.D. Medical College of Ohio, Cincinnati, 1856; a surgeon in the Army during the Civil War and at its close chief surgeon of the Department of the Gulf; instrumental in the organization of the Phillips County (Ark.) Medical Association and also of the Arkansas Medical Society; for many years president of the local board of examiners of pensions, Helena, died at the residence of his brother in Jacksonville, Ala., January 27, from cerebral hemorrhage, after an illness of two years, aged 77.

John C. Spray, M.D. Chicago Medical College, 1873; of Chicago; from 1878 to 1889 medical superintendent of the Cook County Hospital for the Insane, Dunning; an alienist of national repute and one of the earliest advocates of the idea that amusement should not be overlooked in the treatment of the insane, died at the People's Hospital, Chicago, February 20, from pneumonia, after a short illness, aged 60.

Thomas G. Wright, M.D. Albany (N. Y.) Medical College, 1896; a surgeon in the New York National Guard assigned to the Second Regiment, Company D, died at his home in Troy, N. Y., from cerebral hemorrhage, after a long illness, aged 32. He was a member of the Rensselaer County Medical Society and of the Medical Society of Troy and Vicinity.

Harry M. Nickerson, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1889; a member of the American Medical Association; for two years city physician of Portland, and for two years surgeon of the Maine Naval Reserve, died in the Maine Insane Hospital, Augusta, February 2, aged 41.

Oscar Wiley Woods, M.D. University of Virginia Medical Department, Charlottesville, 1898, assistant surgeon U. S. Army,

who saw service in Cuba during the Spanish-American War and afterward served three years in the Philippine Islands, died at the home of his brother in Roanoke, Va., from tuberculosis, February 10, after a long illness, aged 35.

Robert S. Kennedy, M.D. Jefferson Medical College, Philadelphia, 1866, of New Sheffield, Pa., for nearly thirty years editor of the *Beaver County Star*, died at the home of his sister in Spring Garden, Pa., February 8, from cerebral hemorrhage, aged 64.

Thomas B. Hunt, M.D. University of Louisville Medical Department, 1864, assistant surgeon in the Fifty-fourth Kentucky Mounted Volunteer Infantry during the Civil War, died at his home in Warsaw, Ill., Nov. 16, 1905, from rheumatic endocarditis, after an illness of four days, aged 75.

James E. Miller, M.D. Missouri Medical College, St. Louis, 1881, died recently at his home in Louisiana, Mo., and was buried February 1. The physicians of Louisiana at a meeting February 2 unanimously adopted a resolution setting forth their respect and esteem for their deceased brother.

Francis Griffin, M.D. Rush Medical College, Chicago, 1869; a veteran of the Civil War; for many years treasurer for the local school district, died at his home in Mapleton, Iowa, February 6, from heart disease, after an illness of two years, aged 59.

George Janeway Howell, M.D. the University and Bellevue Hospital Medical College, New York City, 1901, a member of the Perth Amboy (N. J.) Board of Health, died at his home in that city, February 3, from pneumonia, aged 25.

Daniel M. MacMartin, M.D. College of Physicians and Surgeons in the City of New York, 1877, a specialist in diseases of the eye, ear, nose and throat, died at his home in Spokane, Wash., from valvular heart disease, aged 52.

Noble W. Mountain, M.D. State University of Iowa College of Medicine, Iowa City, 1873, a member of the Medical Society of the State of California, died recently at his home in Placerville, Cal., and was buried February 4.

Joseph Foulke, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1854, of Philadelphia, died at the home of his daughter in Milwaukee, February 10, after an illness of two weeks, aged 79.

Ogden Backus, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1883, of Rochester, N. Y., died at the City Hospital, Rochester, from postoperative pneumonia, February 10, aged about 50.

William M. Shoemaker, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, died at his home in Georgetown, Washington, D. C., February 8, after an illness of more than a year, aged 83.

Florence De Hart, M.D. Women's Medical College of the New York Infirmary, New York City, 1893, resident physician of the State Home for Girls, Trenton, N. J., died suddenly in that city, February 12, from intestinal disease.

E. F. Darby, M.D. Hospital College of Medicine, Louisville, Ky., 1884, formerly a practitioner of Columbia, S. C., died at his home in Lynchburg, S. C., February 9, after a short illness.

John Findlay Warren, M.D. McGill University Medical Department, Montreal, 1896, of Leeds, N. D., died at a hospital in Fargo, February 10, from hemorrhage of the lungs, aged 37.

Harry Y. Graham, M.D. Cincinnati College of Medicine and Surgery, died at his home in Winton Place, Cincinnati, February 10, from dropsy, after a prolonged illness.

Culvin Force Violette, M.D. University of Louisville Medical Department, 1813, died at his home near Napoleon, Ky., January 10, from senile debility, aged 86.

Reuben B. Mayes, M.D. Memphis (Tenn.) Hospital Medical College, 1886, died at his home in Myrtle, Miss., February 4, from pneumonia, after a short illness.

Samuel C. Latham, M.D. College of Physicians and Surgeons of Keokuk, Iowa, 1870, died at his home in Enfield, Ill., after a long illness, January 28, aged 72.

James G. Conner, M.D. Rush Medical College, Chicago, 1867, health officer of Ionia, Mich., died suddenly at his office in that city, and was buried February 11.

J. E. Mann, M.D. Hahnemann Medical College and Hospital, Chicago, 1881, of Louisville, Ky., died in Liberal, Kan., February 5, after a long illness.

William A. Iahn, M.D. College of Physicians and Surgeons, Baltimore, 1882, died suddenly at his home in Baltimore, February 14, aged 49.

Robert C. Pearson, M.D., New York University, New York City, 1860, assistant surgeon of the Fifty-eighth North Carolina Infantry, C. S. A., died at his home in Morganton, N. C., January 28, aged 68.

William Wakefield, M.D., University of Louisville Medical Department, 1859, died at his home in Humboldt, Kan., January 30, aged 83.

F. M. Attlebury, M.D., Missouri Medical College, St. Louis, 1896, died at his home in Needmore, Mo., January 28, from pneumonia.

Deaths Abroad.

A. Filippi, M.D., professor of medical jurisprudence at Rome, and author of popular manuals on the subject, died at Rome, December 30, aged 69.

D. Chiara, M.D., professor of obstetrics and gynecology at Florence from 1883 to 1893, died at Turin, December 8, after ten years of illness, aged 68.

J. V. Wichmann, M.D., professor of pediatrics at Copenhagen, died recently. His name is familiar to readers of Scandinavian medical literature to which he was a frequent contributor.

E. Pasquali, M.D., president of the Italian Obstetrical Society and director of the gynecologic clinic at Rome, died at Rome, January 5, aged 81. He was professor of obstetrics for thirty-five years, and a pioneer in gynecology in Italy.

J. Cnopf, M.D., died at Nuremberg recently, aged 84. He was a leading spirit in professional matters, a popular pediatrician and a frequent contributor to periodical literature to the very last. His youthful vigor at his advanced age was frequently remarked.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending Feb. 17, 1906:

Hoff, John Van R., asst.-surgeon-general, relieved from further duty at Fort Leavenworth, Kan., and, on expiration of leave of absence, to proceed to Omaha, and report to the commanding general, Department of the Missouri, for duty as chief surgeon of that department.

Bushnell, Geo. E., surgeon, Munson, E. L., and Hutton, Paul C., asst.-surgeons, appointed members of a board of officers to meet at the General Hospital, Fort Bayard, N. M., March 12, for the examination of such officers of the medical department as may be ordered before it to determine their fitness for advancement.

Barney, Chas. N., asst.-surgeon, ordered to report on March 12, 1906, to Major Bushnell, surgeon, president, examining board, General Hospital, Fort Bayard, N. M., for examination to determine his fitness for advancement.

Reynolds, Charles R., Hutton, Paul C., Dale, Frederick A., Roberts, William M., and Farr, Charles W., asst.-surgeons, are advanced from the grade of first lieutenant to that of captain, with rank from Feb. 11, 1906.

Hallack, H. M., surgeon, sick leave of absence extended 50 days. **Woodson, R. S.**, surgeon, ordered to proceed from Fort McJannet, Cal., to Presidio of San Francisco, to accompany detachment of First Battalion, 4th Infantry, to Fort Slocum, N. Y. On completion of this duty Major Woodson will return to his proper station.

Stephenson, William, surgeon, granted 30 days' leave of absence. **Millickin, John D.**, dental surgeon, arrived at Fort Leavenworth, Kans., for duty.

Wortendicker, Clark L., contract surgeon, returned to Madison Barracks, N. Y., from leave of absence.

Peck, Luke B., contract surgeon, returned to Fort Andrews, Mass., from leave of absence.

Shellenbarger, James E., contract surgeon, relieved from duty at Fort Sam Houston, Texas, and ordered to Fort Ringgold, Texas, for duty.

Macy, Fred S., contract surgeon, arrived at Fort Adams, R. I., for duty.

Dier, Albert H., and **Dickenson, Clarence F.**, contract surgeons, left San Francisco on transport *Urcade* for Philippine service.

Davis, Oscar F., contract surgeon, relieved from duty at Jefferson Barracks, Mo., and ordered to duty at Fort Des Moines, Iowa.

Purnell, Julius M., contract surgeon, arrived at Fort McJannet, Cal., for duty.

Richardson, William H., contract surgeon, returned to Fort Sheridan, Ill., from leave of absence.

McCullum, Francis M., contract surgeon, granted leave of absence for one month.

Dougherty, James C., contract surgeon, relieved from duty at Fort Slocum, N. Y., and ordered to Fort Jay, N. Y., to accompany 8th Infantry thence to Philippine service.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending Feb. 17, 1906:

Marsteller, F. H., surgeon, detached from the *Columbin* and ordered home to wait orders.

Page, J. E., surgeon, detached from the *Franklin* and ordered to the *Columbin*.

Stone, E. P., surgeon, detached from the Naval Academy and ordered to the *Rhode Island*, February 19.

Kerr, D. B., surgeon, detached from the *Boston* and ordered home to wait orders.

Bell, W. H., surgeon, ordered to the *Nevada*, February 24.

Cook, F. C., surgeon, detached from the *Nevada* and ordered to the Naval Academy.

Richardson, R. R., P. A. surgeon, detached from the Naval Hospital, Mare Island, Cal., and ordered to the *Boston*.

Porter, F. E., asst.-surgeon, detached from the Naval Hospital, New York, N. Y., and ordered to the *Rhode Island*, February 19.

Logan, F. M., P. A. surgeon, detached from the Naval Hospital, Yokohama, Japan, and ordered home to wait orders.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended February 14:

Irwin, Fairfax, surgeon, detailed as member of Revenue Cutter Service Refitting Board, to meet in Philadelphia, Pa., February 15, from March 1.

Cunningham, H. S., P. A. surgeon, relieved from duty at San Francisco Quarantine Station, and directed to proceed to Yokohama, Japan, for duty in office of American Consulate, relieving P. A. Surgeon **Donald Moore**.

Robertson, H. McF., assistant surgeon, detailed as member of Revenue Cutter Service Refitting Board to meet in Philadelphia, Pa., February 15.

Booley, C. A., acting asst.-surgeon, granted thirty days' leave of absence from February 13.

Bullard, J. T., acting asst.-surgeon, granted leave of absence for thirty days from February 13.

Health Reports.

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended February 16, 1906:

SMALLPOX—UNITED STATES.

California: San Francisco, Jan. 27-Feb. 3, 21 cases, 2 deaths. District of Columbia: Washington, Feb. 3-10, 1 death. Florida: Jacksonville, Feb. 3-10, 2 cases, 1 death; Ocala, 2 cases; Espanola, 3 cases. Georgia: Augusta, Feb. 6-12, 5 cases. Indiana: Allen County, Dec. 1-31, 1 death. Kentucky: Covington, Feb. 3-10, 1 case. Louisiana: New Orleans, Feb. 3-10, 4 cases. Maryland: Baltimore, Feb. 3-10, 7 cases. Missouri: St. Louis, Feb. 3-10, 6 cases. Ohio: Cincinnati, Feb. 2-9, 7 cases. South Carolina: Georgetown, Feb. 15, 1 case (imported). Tennessee: Memphis, Jan. 24-Feb. 7, 5 cases, 1 death. Wisconsin: Appleton, Feb. 3-10, 1 case; La Crosse, 1 case.

SMALLPOX—FOREIGN.

Brazil: Pernambuco, Dec. 15-31, 39 deaths. New Brunswick: Kings County, Feb. 4, present; Queen's County, present; Sanbury County, present. Y. county, present. Canada: Toronto, Jan. 27-Feb. 3, 1 case. China: Shanghai, Dec. 23-30, 1 death. France: Paris, Jan. 27-Feb. 2, 13 cases, 2 deaths. Gibraltar: Jan. 1-Feb. 4, 5 cases. Greece: Athens, Jan. 8-15, 1 death. India: Bombay, Jan. 9-16, 2 deaths; Calcutta, Dec. 30-Jan. 6, 61 deaths; Karachi, Jan. 7-14, 4 cases, 4 deaths; Madras, Jan. 6-12, 19 deaths; Rangoon, Dec. 30-Jan. 6, 19 deaths. Italy: General, Jan. 18-25, 66 deaths. Japan: Fomosa, Dec. 1-31, 3 cases. Russia: Moscow, Dec. 23-Jan. 13, 5 cases, 3 deaths; Odessa, Jan. 13-27, 38 cases, 4 deaths; St. Petersburg, Dec. 30-Jan. 20, 19 cases, 7 deaths. Spain: Barcelona, Jan. 21-31, 7 deaths.

YELLOW FEVER—FOREIGN.

Cuba: Habana, Feb. 11, 1 case. Honduras: El Paraiso, Jan. 19, 1 death. Mexico: Merida, Jan. 28-Feb. 3, 2 cases, 2 deaths; Vera Cruz, Jan. 21-27, 2 cases, 2 deaths. Nicaragua: Managua, Dec. 23-30, 1 death.

CHOLERA—FOREIGN.

India: Calcutta, Dec. 30-Jan. 6, 72 deaths; Madras, Jan. 6-12, 1 death; Rangoon, Dec. 30-Jan. 6, 3 deaths. Russia: Government of Lomza, Jan. 4-14, 6 cases, 2 deaths; Government of Plock, Dec. 18-29, 21 cases, 13 deaths.

PLAGUE—INSULAR.

Hawaii: Kaula, Feb. 13, 2 deaths.

PLAGUE—FOREIGN.

Africa: Mozambique, Nov. 19-Dec. 6, 3 deaths. Total to Dec. 6, 78 cases, 28 deaths. India: Bombay, Jan. 9-16, 24 deaths; Calcutta, Dec. 30-Jan. 6, 25 deaths; Karachi, Jan. 7-14, 9 cases, 8 deaths; Madras, Jan. 6-12, 1 death; Rangoon, Dec. 30-Jan. 6, 30 deaths. Japan: Fomosa, Dec. 1-31, 13 deaths; Kagiwa Ken, to Jan. 10, 2 cases; Kobe, 34 cases; Nara Ken, 2 cases; Osaka, 140 cases; Yamaguchi (Shimonoseki) 8 cases, 1 death. Mauritius, Dec. 14-28, 7 cases, 5 deaths. Persia: Solistan, Jan. 18, 200 deaths.

Book Notices

INFANTILE MORTALITY AND INFANTS' MILK DEPOSITS. By G. F. McCleary, M.D., D.P.H., Medical Officer of Health of the Metropolitan Borough of Battersea. Cloth, Pp. 135. Price, 6 shillings net. London: P. S. King & Son, 1905.

This book deals with the problem of infant mortality and the measures taken to reduce it in various countries, in France, England and the United States. Attention is called at the outset to the declining birth rate, both in England itself and in one of the colonies, especially Australia. It is a declining fertility which has evidently stimulated McCleary to write the book. He points out the urgent necessity of reducing the high mortality among infants in order to offset the low birth rate, and in discussing the causes of this high mortality gives the chief place to improper feeding. To correct this he lays down two general principles: First, a more general encouragement of breast feeding, and, second, where this is impossible the provision of a pure, properly prepared cow's milk. The elaboration of these two principles constitutes the bulk of the book, and while throughout due emphasis is laid on the superiority of breast feeding, McCleary concerns himself mainly with a discussion of the methods in vogue to attain the second, i.e., the supply of a pure substitute food. This resolves itself into a detailed account of the now well-known "milk laboratories," "stations" or "depots" as they are conducted in different countries.

Two institutions in France are first described; the *Consultation de Nourrissous* and the *Goutte de Lait*. The former has for its chief object the encouragement of breast feeding, food and money prizes being awarded to nursing mothers whose infants make satisfactory progress, the mothers with their infants reporting at stated intervals to a dispensary or hospital. As a natural development from this institution arose the *Goutte de Lait*, the purpose of which is the provision of a pure milk, whole or modified, to such infants as have been deprived of their natural food supply. Rigid medical oversight of the infants is maintained in both of these organizations; if they do not report regularly the milk is stopped.

The American laboratories are next described, the Strauss stations in New York being taken as a type. Lastly, the English "depots" are described much in detail. McCleary considers these various institutions in the order in which he apparently thinks they have been established, but makes no mention of the first one of the kind ever started, that in Boston in the summer of 1890 under the direct supervision of Rotch. The first *Goutte de Lait* is reported as being established in Paris in 1892, the first "depot" in England in 1899. The wide distribution of these stations is evidenced from the list given, showing their establishment throughout England, in Europe, North and South America. Most of the English "depots" are under municipal control, all in America under private control except the one at Rochester, which is a municipal organization. This is mentioned in high terms by Dr. McCleary as being superior to any similar "depot" in England. One of the best features of this laboratory, by the way, is the modifying which is done at the farm in the country. The importance of the farm and dairy end of the milk problem is duly emphasized throughout the book.

The work as a whole is an extremely interesting account of the world-wide movement for a better and purer milk for infants, a movement arising in France and England from a contemplation of the declining birth rate and the consequently greater necessity of preserving the infants actually born, and arising in the United States from humanitarian motives, pure and simple. It is of interest mainly, however, to health officials and to those pediatricians actively engaged in obtaining for city infants a supply of pure milk. It is of no help to a physician in solving the problem of a given case of difficult feeding. No details are given. To those familiar with the methods in vogue in American cities there is nothing new in the book, and they will derive but little help in solving the problem of city milk. In this respect at least our confrères across the water have taken a leaf out of the Yankee book and adapted an American institution to their own municipal peculiarities.

A TEXT-BOOK OF THE DISEASES OF THE EAR, NOSE AND PHARYNX. By D. B. St. John Roosa, M.D., LL.D., and B. Douglass, M.D. Cloth, Pp. 621. Price, \$3.00 net. New York: The MacMillan Co., 1905.

This volume contains over ninety pages devoted to the anatomy and a brief review of the physiology of the ear. The subject of foreign bodies in the ear is set forth very fully and in a most interesting manner. Eighty-two pages are devoted to the diseases of the nose, throat and nasopharynx, to which so many aural affections owe their origin. This section is fairly complete, although the student might desire somewhat fuller directions. Thus, speaking of cauterization of the turbinates, "a flat nasal electrode attached to a proper electric apparatus" is recommended. And when enlarged tonsils are present with adenoids the authors advise the removal of the tonsils before attacking the adenoids, but do not express any preference as to the method. Their reasons for dividing chronic non-suppurative inflammation of the middle ear into catarrhal and proliferous inflammation, and the diagnosis between both and diseases of the labyrinth by means of the tuning-fork, are elaborated. They protest against the tendency of some neurologists to call all cases in which vertigo is a symptom Ménière's disease, and would limit the term to disease of the labyrinth. Various radical operations, including Roosa's, for mastoid disease are described in detail. A chapter on deaf-mutism, with suggestions for the mechanical relief of deafness, closes the volume. There are 108 cuts illustrating the text, but in a few cases the letters referred to in the legends are lacking. The text is generally clear and the diction good. We find a few long, involved sentences, such as the second paragraph on page 340. A few grammatical and rather numerous typographical errors will no doubt be corrected in subsequent editions. The book may be recommended as a safe guide.

THE PATHOLOGY OF THE EYE. By J. H. Parsons, B.S., D.Sc. Vol. II. Histology.—Part II. Cloth, Pp. 770. Price, \$3.50. New York: G. P. Putnam's Sons, 1905.

In the second volume of this elaborate work Mr. Parsons has placed the science of medicine in general and that of ophthalmology in particular under a deep obligation. He reviews and profusely illustrates the histology of the crystalline lens, the vitreous, choroid, retina, optic nerve, orbit and the lacrimal apparatus. It must be borne in mind that the histology spoken of refers not only to normal conditions but to pathologic ones, so that this work is practically a textbook dealing with abnormal conditions generally found in the structures mentioned. Probably the most valuable portion of the work is that touching the various tumors of the eye, and we know of no monograph on the subject that compares with it in a practical demonstration of the changes found in this class of tissue alteration. Although the micro-photographs and illustrations generally are no better in quality than those seen in other books of the kind, they serve their purpose very well, and even when only diagrammatic, are useful. We especially commend the index of illustrations and think that many other writers might well take a leaf from Mr. Parsons' monograph in this particular. Space does not permit a reference to the many important original observations of the author, but we can not refrain from drawing the reader's attention to the elaborate descriptions of choroidal changes, especially of the neoplasms, and affect that membrane. We are certain that the work will long stand as an important contribution to the pathology as well as to the normal histology of the eye.

A SYSTEM OF MEDICINE. By Many Writers. Edited by T. C. Allbutt and H. D. Rolleston. New Edition. Revised Throughout with Additions. Vol. I. Cloth, Pp. 1209. Price, \$5.00. New York: The MacMillan Co., 1905.

This is the first volume of the second edition of this system. It is the intention of the authors to revise and bring out one volume a year, each new volume corresponding to one of the first edition, so that the original edition will gradually be superseded by the new. Besides the prolegomena, Volume I contains some of the acute affections, such as erysipelas, influenza, diphtheria, infective endocarditis, cerebrospinal fever and enteric fever. Cholera and plague have been transferred to the tropical medicine section. The first article, on the history of medicine, is a new contribution by Allbutt. The article on medical statistics has been rewritten entirely. The arrangement of the article on dietetics has been altered somewhat, and

this chapter also contains a section on the physiologic principles of dietetics. New articles on exercise in the treatment of disease and on x-rays are added. The chapter on the clinical examination of the blood and its significance is contained in this volume, while the article on atherothrombosis has been transferred to another volume. Among other things discussed in Volume I are climate in the treatment of disease, massage, hydrotherapy, the hygiene of youth, principles of drug therapeutics, old age, life insurance, inflammation, fever, the general pathology of nutrition and of new growths, and nursing.

BACTERIOLOGY OF PERITONITIS. By L. S. Dudgeon, M.R.C.P., and P. W. G. Sargent, M.A., M.B., B.C., F.R.C.S. Cloth. Pp. 243. Price, \$2.50 net. Chicago: W. T. Keener & Co. 1905.

The authors state that they have attempted to place the bacteriology of acute peritonitis on a sound basis, and to deduce from the knowledge thus gained some facts which may serve to guide the surgeon in the treatment of the various diseases which are grouped under the names of septic or suppurative peritonitis. The relationship of the various affections of the contents of the abdomen to peritonitis are discussed at great length, and the rôle of the phagocytes in peritonitis also receives considerable attention. Speaking of the treatment of this condition, the authors state that the question between local irrigation and dry sponging, carried out with gentleness, is better than irrigation. The question of drainage, drug and serum treatment are discussed briefly. The authors believe that in the large majority of cases of acute peritonitis it is the colon bacillus which kills the patient. The only serum, therefore, which would be of value in helping to diminish the mortality of peritonitis is a multivalent anti-coli serum. The indiscriminate use of antitoxic sera is condemned as being both useless and unscientific.

PATHOGENIC MICRO-ORGANISMS INCLUDING BACTERIA AND PROTOZOA. A Practical Manual for Students, Physicians and Health Officers. By W. H. Park, M.D., assisted by A. W. Williams, M.D. Second Edition, Enlarged and Revised. 165 Illustrations. Cloth. Pp. 556. Price, \$3.75. New York: Lea Brothers & Co., 1905.

The most notable feature of this volume is the part devoted to the protozoa. Hitherto textbooks on bacteriology have failed to recognize the importance of animal organisms in the causation of disease. Obviously it is advisable that these organisms should be discussed together with the vegetable organisms. Sixty pages are devoted to the discussion of the ameba, trypanosomes, the spirochetes of relapsing fever and syphilis, the malarial organisms and the protozoan-like bodies found in smallpox and allied diseases. In the appendix the author discusses the agglutinins, the hemolysins, the diplo-bacillus of Morax-Axenfeld and the relation of the stegomyia to yellow fever. The part on bacteria also has been revised carefully, thus making the work a valuable summary of the present-day knowledge in this field of medicine.

A TEXT-BOOK ON THE PRACTICE OF GYNECOLOGY. For Practitioners and Students. By W. Easterly Ashton, M.D., LL.D., Professor of Gynecology in the Medical-Chirurgical College of Philadelphia. Octavo. 1,079 pages, with 1,046 Original Line Drawings. Price, \$6.50 net. Philadelphia: W. B. Saunders & Company, 1905.

Ashton appreciates that the average young practitioner has received only most superficial information regarding the technique of gynecologic operating and the diagnosis of diseases of women. He therefore takes up clearly and succinctly each step of each procedure, so that it is impossible to misunderstand his meaning. In place of the routine practice of devoting a general chapter or chapters to physical examination the author details the method of examinations of each organ before considering its diseases. More than a thousand illustrations are shown, none of which is old or hackneyed; all are new line drawings made from apparatus, living models, the cadaver or the descriptions of operations by other operators. The book will be found decidedly practical.

THE SURGEON-GENERALS OF THE ARMY OF THE UNITED STATES OF AMERICA. A Series of Biographical Sketches of the Senior Officers of the Military Medical Service from the American Revolution to the Philippine Expedition. By James Evelyn Pilcher, M.D., Ph.D., LL.D., Major and Surg. U. S. V.; Cap. Ret. U. S. A.; Secretary of the Association of Military Surgeons, and Editor of the *Journal of the Association of Military Surgeons of the United States*, Nov. 1904. Cloth. Pp. 144. Carlisle, Pennsylvania, The Association of Military Surgeons, 1905.

In addition to well written and comprehensive articles on the surgeon-generals of the United States Army, Major Pilcher

has given us in this book biographic notices, with portraits, of Samuel Preston Moore, surgeon-general of the Confederate Army; of James McHenry and William Eustis, military surgeons who became secretaries of war, and of Benjamin Rush, the whole constituting a volume of interest not alone to the military medical officers but to the profession at large. All interested in the lives and achievements of medical men who have helped in the making of the history of this country will find recreative reading in this book.

DOSE-BOOK AND MANUAL OF PRESCRIPTION-WRITING, with a List of Official Drugs and Preparations and Many of the Newer Remedies with Their Doses. By E. Q. Thornton, M.D., Ph.G. Third Edition, Revised and Enlarged and Adapted to the Eighth Revision (1905) of the United States Pharmacopoeia. Flexible Leather. Pp. 392. Price, \$2.00 net. Philadelphia: W. B. Saunders & Co., 1905.

This book is of value to the student as a guide to the proper construction of the prescription. It includes directions for converting the apothecary weights into the metric system, and vice versa. That part devoted to prescription writing and incompatibilities is of especial value. The appendix includes a list of the common poisons and methods of treatment of poisoning. This edition also contains a list of the drugs with their doses arranged in accordance with the recent changes established by the new Pharmacopoeia.

MASSAGE AND THE ORIGINAL SWEDISH MOVEMENTS, their Application to Various Diseases of the Body. By K. W. Ostrom. Sixth edition, revised and enlarged, with 115 illustrations. Cloth. Pp. 184. Price, \$1.00. Philadelphia: P. Blakiston's Son & Co., 1905.

The physician's knowledge of the general methods of massage, together with his familiarity with anatomy and physiology, enable him to work out the details of mechanical treatment, but he would far better have some such book as this by Ostrom as a guide. Details are given for massage of all portions of the body and the illustrations make it easy to understand the directions. This sixth edition has been thoroughly revised and a number of new portions added. The physician who is not using any of these methods in his treatment is omitting a valuable part of the therapy that is open to him.

A TEXT-BOOK OF LEGAL MEDICINE. By Frank Winthrop Draper, A.M., M.D., Professor of Legal Medicine in Harvard University. Fully Illustrated. Cloth. Pp. 573. Price, \$4.00 net. Philadelphia: W. B. Saunders & Co., 1905.

Draper writes with the inspiration of his own realization of the importance of the subject. He urges on the medical student careful study, because of the likelihood of medicolegal complications in the first case undertaken in his practice. Draper feels that not enough attention is paid to this subject in medical colleges. The reader finds in this book the sympathy of a man of wide experience and most practical ways of viewing things. The book has been carefully kept within reasonable limits, and except for the departments of toxicology and psychiatry will be found a full text-book on medicolegal affairs.

LEHMANN'S MEDIZINISCHE ATLASSEN. Band V. Atlas Typischer Röntgenbilder vom normalen Menschen. By Dr. med. Rudolf Graschew. Mit 97 tafelförmigen (Autotypen) in Originalgrösse und 42 Konturzeichnungen (davon 11 als Uebersichtsbilder), ferner 14 schematischen Figuren im Einleitungsstext. Cloth. Pp. 92. Price, \$4.00. Munich: J. H. Lehmann's Verlag, New York: P. B. Hoeber.

This atlas consists of 97 reproductions of radiographs of the various parts of the body, particularly of joints, which are likely to be injured by a trauma and in which the diagnosis may be subject to doubt. Each illustration is accompanied by a suitable explanatory text. The book also contains 42 outline drawings and 14 diagrammatic sketches. The radiographs are excellent and the work can not fail to elicit the appreciation of those who are interested in roentgenology.

VITAL QUESTIONS. By H. D. Chapin, M.D. Cloth. Pp. 189. Price, by mail, \$1.10. New York: T. Y. Crowell & Co.

The title of this volume may be amplified by saying that the work discusses the fundamental problems of the physician's life and activity. Some of the "Vital Questions," as subdivided by chapters, are: "Unequality—the Question of Opportunity"; "The Unit—the Question of Survival"; "Poverty—the Question of Subsistence"; "Success—the Question of Achievement"; "Death—the Final Question," etc. The entrance of the physician into politics, into work for social betterment, into medical society work, etc., is due to his thought on these same problems which Chapin discusses. This book will stimulate the endeavor to be of service to humanity.

SPERMANN'S HISTORISCHER MEDICINAL-KALENDAR, bearbeitet von Prof. Dr. J. Pagen und Prof. Dr. J. Schwabe in Berlin. Paper, Pp. 184. Price, 75c. Munich: J. F. Lehmann's Verlag. New York: P. B. Hoeber.

This calendar is in the form of a tablet, each leaf of which represents two days of the year. At the head of each page is a reproduction either of a famous painting dealing with some medical subject or of some well-known caricature drawing or the portrait of a medical celebrity. Besides this, under each date are noted one or more occurrences of importance in medicine, the announcement of the birth or death of a man prominent in research work and in practice, and pertinent aphorisms. Many astronomical data are also recorded.

SKIASCOPY AND ITS PRACTICAL APPLICATION TO THE STUDY OF REFRACTION. By E. Jackson, A.M., M.D. Fourth Edition. Revised and Enlarged, with 28 Illustrations. Cloth. Pp. 117. Denver: Herlick Book and Stationery Co., 1905.

With a view to making this little treatise more complete, Jackson has added two chapters, one on exact skiagraphy and the other on auto-skiagraphy. In the first chapter are discussed the procedures necessary to render skiagraphy valuable, such as the dark room, the source of light, mirror, etc. In the second chapter the reader is instructed how to measure his own refraction by the use of an ordinary looking-glass, in addition to the apparatus commonly employed for the test.

MATERIA MEDICA AND THERAPEUTICS. An Introduction to the Rational Treatment of Disease. By L. M. Bruce. New and Enlarged Edition. Cloth. Pp. 632. Price, \$1.75 net. Chicago: W. T. Keener, 1905.

A change, which the author believes will be regarded as an improvement, is the introduction of greater detail respecting the chemical and pharmaceutical relations of the individual drugs. An entirely new part has also been added, containing an account of the materia medica and therapeutics of the drugs mentioned in the Indian and Colonial Addendum to the *British Pharmacopæia*.

READY REFERENCE HANDBOOK OF DISEASES OF THE SKIN. G. T. Jackson, M.D. 91 Illustrations and 3 plates. Fifth edition. Cloth. Pp. 676. Price, \$2.75 net. Philadelphia: Lea Brothers & Co., 1905.

The present edition is considerably larger than the preceding one because of the addition of new sections on affections of the skin recently recognized. As heretofore, the symptoms, diagnosis and treatment are especially considered, and the alphabetical arrangement of the diseases, a feature which has made this work popular, is preserved. Many new prescriptions have been added to the appendix.

A MANUAL OF BACTERIOLOGY. By H. P. Williams, M.D. Revised by E. M. Bolton, M.D. 108 Illustrations. Fourth Edition, Revised and Enlarged. Cloth. Pp. 357. Paper, \$1.75. Philadelphia: P. Blakiston's Son & Co., 1905.

This edition maintains the characteristic features of previous editions, but contains many additions, especially in the chapters on bacterial poisons and on immunity. The appendix is devoted to a consideration of several pathogenic protozoa, the *Amœba dysenterica*, the *Plasmodium malarie*, trypanosomes and organisms found in smallpox and vaccinia.

PHYSICAL DIAGNOSIS. Including Diseases of the Thoracic and Abdominal Organs. A Manual for Students and Physicians. By E. Le Veure, M.D. Second Edition, Revised and Enlarged. Cloth. Pp. 479. Price, \$2.25 net. Philadelphia: Lea Brothers & Co., 1905.

Among the new features of this edition are the very complete revision of the chapter on topographic and rational anatomy and the many new illustrations, including a number of radiographs of diseases of the heart and aorta. Such revisions as were necessary to bring the work up to date have been made.

OIL WELLS IN THE WOODS. By J. C. O'Day, M.D. With Illustrations by Miss Ethel Farmer, and Photographs Collected by the Author. Cloth. Pp. 359. Deposit, N. Y.: The Oquana Press, 1905.

Dr. O'Day has written a tale that is interesting, but which is not notable for literary merit. The love story is woven about scenes in the oil wells of Pennsylvania, and its decided local flavor gives evidence of the author's intimate knowledge of the oil fields.

Catatonia. Mouratoff after a critical study of this type of mental ailment and of its literature concludes that it is entitled to be considered rather as a morbid species by itself, with a somewhat definite though varied symptomatology, but with one symptom always constant, and a generally constant termination in dementia.

Miscellany

Graft.—Not many years since, a half-page advertisement of a sanitarium appeared in a well-known medical journal, offering stock of the sanitarium company on very advantageous terms to doctors sending patients to that institution. It did not lessen the insult of this intimation to learn that the leading spirit of the sanitarium company was a fellow of a learned medical organization of this state. A certain mineral springs company has recently, it is said, offered its stock to physicians, so as to induce them to advocate the use of its waters to their patients. Who does not know that in this city some oculicians give, and some oculists shamefully accept, commissions on sales made to patients? The public should realize that an oculist, who insists on his patients buying their glasses at one or two special stores, lays himself open to the suspicion of being bribed to do so by a commission from the dealer. The same suspicion attaches to the doctor who unduly urges patients to buy medicines from one apothecary. It is true that spectacles and medicines should be accurately made and compounded; but there are usually too many reliable dealers, especially in large cities, to necessitate so restricted a choice for the mere benefit of the patient. Another scheme, to impose on the patient and extract from him what is practically two fees, consists in giving him a prescription for medicine under a special name, agreed on by the doctor and the druggist with whom he is in collusion. The patient is then obliged to go to the apothecary mentioned by the doctor, even if it be several miles out of his way, under the impression forsooth that no other apothecary prepares the remedy so carefully. This business enterprise is not unlike that practiced by some hospitals, which, to obtain a large and interesting accident service, keep beer and whisky ready for the men running the patrol wagon. Little wonder is it that the injured are at times driven many unnecessary squares and that certain institutions can show an unusually long list of accident cases. Whether these institutions similarly profit by using their private wards and rooms as boarding houses for members of state legislatures and their friends, who visit the centers of gayety for pleasure or business, need not be discussed in this paper.—J. B. Roberts.

The Logical Basis of the Sanitary Policy of Mosquito Reduction.—Sir Donald Ross, in *Science* (vol. xxi, No. 570, page 689, Dec. 1, 1905), said that the life of gnats, like that of other animals, is governed by fixed laws. Local reduction, that is, artificial reduction of the density of population, practically resolves itself into (a) direct destruction, and (b) artificial creation of unfavorable conditions. Suppose a box containing a million gnats were to be opened in the center of a large plain, and that the insects were allowed to wander freely in all directions. During the first minute most of the insects would fly toward every point of the compass. At the end of a minute a few might fly straight on and a few straight backward, while the rest would travel at various angles to the right or left. At the end of the second minute the same thing would occur. At last, after their death, it would be found that an extremely small proportion of the insects had moved continuously in one direction; and that the majority of them had wandered more or less backward and forward and had died in the vicinity of the pool or box from which they originally came. The law determining the behavior of these insects may be called the centripetal law of random wandering. It obtains that when living units wander from a given point, guided only by chance, they always tend to revert to that point. Mosquitoes guided either by chance or by search for food are not likely to wander continuously in one direction. They will always tend to persecute most those houses which lie in the immediate vicinity of their breeding pool. This is not understood by many who think that mosquitoes radiate as rays of light from a center, and argue that, therefore, it is useless to drain local breeding pools because of the influx of mosquitoes from without. Such an influx certainly exists, but it can not generally compensate for local destruction. Consider a tract of country over which numbers of mosquito-breeding pools are scattered, with houses and other feeding places lying among them. Drain away all

the pools to the right of a straight line drawn across this country, leaving all those to the left of it intact. How many mosquitoes will there now be on the right side, compared with those on the left side? We suppose that, before the drainage was effected, mosquitoes were then breeding fairly uniformly over the whole country; that there was a certain amount of migration across the line, both ways; and since the density was equal on both sides, this migration must also have been equal and opposite—that is, as many emigrants must have been constantly passing from right to left as from left to right. After drainage the following changes would occur: The insects breed as before on the left side of the line, and some continue as before to cross over into the drained country; but in the latter, on the right of the line, propagation is entirely checked and the migration from it to the left of the line now ceases. Hence, not only must there be a decrease of mosquito density on the right side of the line, but also a decrease on the left of the line—that is to say, the drainage has affected the mosquito density not only up to the line of demarcation, but beyond it. And moreover, since the migration was formerly equal from both sides of the line, the mosquitoes gained by immigration into the drained country must be exactly lost by the undrained country. The number of immigrants, therefore, into any area of operations must, for practical purposes, be very small or inappreciable a short distance within the boundary line. The effect of wind requires examination. With a wind blowing continuously from one direction, the indication would be to extend the drainage further in that direction. Obviously, wind may scatter mosquitoes, but it can not create them nor prevent the total average reduction due to anti-propagation measures, as some people seem to think. It is, however, very doubtful whether wind does drive or scatter mosquitoes to any great degree; they are extremely tenacious of locality. The statement is often made that mosquitoes are brought into towns in trains, carts and cabs. The number introduced in this manner must always be infinitesimal compared with those that fly in or which are bred in the town itself. Moreover, if vehicles bring them in they may also take them out. In conclusion, as a general rule for practical purposes, if the area of operations be of any considerable size, immigration will not very materially affect the result.

The Proper View to Take in Organization.—We can accomplish nothing outside of co-operative and organized work; and though we fail to realize all we hope for, we can attain much that will improve our present condition. Is it not childish for us to permit personal prejudices and predilections as to methods and men turn us aside from the attainment of this power we so plainly need? All great accomplishments demand the sacrifice of the smaller things for the greater in view; and if we could serve best the great profession to which we belong, and the present generation and those to come who look to us with hope and confidence, we must follow this rule that obtains in all great enterprises. Let us not be too ready to criticize methods and men; we ourselves are fallible. The future will work out many problems that perplex us now; and under broader and more intelligent views the needs will be met and the bad in men and methods will be thrown aside. The more strongly and heartily we combine now for this great object, forgetting the little differences that must come up, the sooner will we accomplish this great purpose. The profession of medicine will rise to a higher plane of proficiency and will occupy a higher place in the esteem of the people.—B. F. Eager, in *Kentucky State Medical Association Bulletin*.

The Right to Use Any Beneficial Method.—The right to select remedies and methods with absolute freedom is so generally recognized by all the so-called schools that sects are sects now only in name. Surgery is alike in all; dietetics and nursing know no school. Homeopathy no longer pretends to administer infinitesimal doses of inversely potentiated medicines, expecting them to produce symptoms like those of the disease treated; eclectics no longer assume to have a monopoly of wisdom in the selection of therapeutic remedies, and physio-medicals can boast of no useful information that may not be known by all. Then why should we not have a united profes-

sion? Many believe that we may have an undivided profession and have declared in favor of union by the simple abandonment of sectarian names. These designations have lost their original meaning, and are retained presumably for some supposed advantage in the proclamation which they make to the public. The constitution of the reorganized state and county societies wisely provides that any reputable physician who will agree to practice nonsectarian medicine shall be eligible to membership in these societies and thereby in the American Medical Association. This has raised the question as to what is implied in the practice of nonsectarian medicine. It is the practice of medicine and surgery without proclaiming to the public that such practice is based on any exclusive method or system. Truth as one sees it is to be the light, judgment as now to be the guide. The only restriction being that one is to refrain from using a sectarian designation which at best serves only to hold out a claim to the public that one has some remedy or method not possessed by our confrères.—*Columbus Medical Journal*.

The Extensor Digitorum Communis Reflex.—A. Morselli (*Rivista di Patologia nervosa e mentale*), has studied this reflex in various pathologic conditions and concludes that it is a phenomenon of muscular reaction dependent on the tone and trophic condition of the nervous centers. It is constantly present in normal individuals and is induced by percussion of certain points near the humeral condyles and on the forearm and appears in the form of extension of the fingers and the hand. It may not be present in children under 3 years and is dulled in old age. In pathologic conditions it may be exaggerated, weakened or abolished. In some nervous affections the intensity of this reflex may be a differentiating symptom, as, for example, between tabes and pseudo-tabes from alcohol, and between traumatic and alcoholic neuritis, since in the toxic forms the muscular reaction is torpid or feeble while in the others it is exaggerated. In hysteria and hystero-epileptic conditions it may be exaggerated while in epileptic states and in some neurasthenies it is weakened and finally abolished. In alcoholic and morphine insanity the reflex is torpid while on the other hand in dementia precox, in paresis and in mania it seems to be exaggerated.

Quacks in Turkey.—The Constantinople correspondent of the *Lancet* states that in Turkey quacks of all kinds flourish. He reports that the Turkish physician, Dr. Nouri Effendi, recently made a tour in the provinces and reported a deplorable state of affairs occasioned by the utter ignorance of the population and the inability to meet the difficulties arising out of different contagious maladies. The people never attach any importance to the first manifestations of the disease, but in later stages they call in all sorts of persons professing to be well versed in occult sciences. These persons attribute every malady to an evil eye. Their routine treatment is to administer a potion of water into which melted lead has been dropped, the draught to be taken during the recital of an incantation. The shapes assumed by the lead dropping into the water are pointed out to have various, generally menacing, significances. Other quacks prescribe a diet which has to be adhered to for 70 days and which consists of dry bread without salt. If the condition disappears the skill of the quack is praised. If the disease persists then it is due to the unhappy star of the patient's destiny. Dr. Nouri Effendi declared also that in consequence of such quackery and ignorance preventable and curable maladies are propagated with disastrous results.

Poisoning of a Child by Strychnin Tablets.—Dr. Vinnege reports in the *Lancet-Clinic*, May 6, 1905, an instructive case indicating the necessity of care in dispensing medicine. A physician left nine red tablets, each containing 1/60 of a grain of strychnin, on a table in a bedroom by a patient, with instructions for their use. The patient, not being confined to bed, left the room some time later, and on her return saw that the pills which had not yet been taken had disappeared. She found that one of the children had swallowed them. The child died. The attending physician, in his sworn statement before the coroner, said that as he went into the house he noticed the children playing in the front room. In spite of this, the dan-

ger of leaving the tablets loose on the table apparently did not occur to him. Dr. Vinmege, who reports the case with the consent of the attending physician for the sake of the warning it contains, quotes from the law of Indiana on the subject, from which it appears that the only restraint and guide the physician has is his reasonable care and diligence." The lesson is obvious that no tablets which would even be harmful to children, should be dispensed in the manner spoken of.

Value of Discussions at Society Meetings.—I must admit that many of these long, so-called original papers I pass over, and simply read the discussions on them. The discussions generally contain the meat of the nut. They cover the ground in a condensed and concise manner. We can in this way obtain a knowledge of the papers read by reading a few words in place of reading a great many. Discussions of papers are usually limited to five minutes. A great deal can be said in five minutes, provided the one speaking confines himself closely to the subject matter. But when he speaks one-half of the time in complimenting the speaker, then some time in excuses, he can not say very much in the two minutes remaining. I think it would be well if the complimentary part was understood, and that no excuse or apologies were made, but let the five minutes be used in actual discussion of the papers.—George J. Munroe, in *Cincinnati Lancet-Clinic*.

Floating Hospital in Northern Africa.—It is reported that the Presbyterian Board of Foreign Missions has established a floating hospital on one of the tributaries of the Nile. In this way medical aid will be given to natives along the shores who suffer from pulmonary and eye diseases. The hospital boat will be equipped with all modern appliances for the treatment of trachoma and other eye diseases, and will make two trips each month from the mouth of the Sohat, a tributary of the Nile, to its source. The boat is named in memory of James A. Elliott.

State Boards of Registration

COMING EXAMINATIONS.

MAINE State Board of Registration of Medicine, City Building, Portland, March 13. Secretary, Wm. J. Maybury, Saco.

CONNECTICUT Medical Examining Board, City Hall, New Haven, March 13-14. Secretary, Charles A. Tuttle, New Haven.

MASSACHUSETTS Board of Registration in Medicine, State House, Boston, March 13-14. Secretary, Edwin B. Harvey, Boston.

Minnesota January Report.—Dr. O. E. Linjer, of the Minnesota State Board of Medical Examiners, reports the written examination held in St. Paul, Jan. 2-4, 1906. The number of subjects examined in was 12; total number of questions asked, 95; percentage required to pass, 75. The total number of applicants examined was 27, of whom 19 passed and 8 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Queen's University, Ontario (1896) 77.1; (1901) 77.5; (1902) 81.4			
Columbia University, New York..... (1905)			85.1
Barnes Med. Coll. (1905)			76.5
University of Minnesota..... (1905) 75, 75.2, 83.5,			83.7
University of Illinois..... (1905)			78.7
McGill University..... (1902)			88.7
Jefferson Med. Coll. (1905)			77.9
Hahnemann Med. Coll. Chicago..... (1905)			77.6
Harvard University..... (1886)			85.5
University of Pennsylvania..... (1905)			81.7
Laval University, Quebec..... (1899)			78.3
Northwestern University..... (1905)			85.8
University of Leipzig, Germany..... (1883)			80.1
University of Michigan, Hooce, Dept. (1904)			85.3
OMAHA Med. Coll. (1902)			69.9
Jefferson Med. Coll. (1897)			74
Hamline University..... (1904) 63.8; (1905) 70.9,			75.1
University of Minnesota..... (1905)			73
Laval University, Quebec..... (1902)			72.2
Rush Med. Coll. (1902)			68.9

FAILED.

* Low mark in the important branches.

New Requirements in Nebraska.—The following resolution, effective July 1, 1906, has been adopted by the Nebraska State Board of Health: "Resolved, That applicants for a license to practice medicine in the state of Nebraska shall present to the board of examiners evidence of having university or college

degree or a high school diploma of college entrance standard or in lieu thereof applicant must pass a satisfactory examination before the state superintendent of public instruction."

South Dakota January Report.—Dr. H. E. McNutt, secretary of the South Dakota Board of Medical Examiners, reports the written examination held at Sioux Falls, Jan. 10-11, 1906. The number of subjects examined in was 12; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 12, of whom 11 passed and 1 failed. Twelve candidates were granted license by reciprocity. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
University of Nebraska..... (1905)			81.6
University of Nashville..... (1905)			75.0
American Coll. of Med. & Surg., Chicago..... (1904)			78.7
University of Toronto..... (1890)			83.7
Creighton Med. Coll. (1905) 82.7, 83.4, 88.7			
College of P. & S. Chicago..... (1905) 77.9, 85.6			
Lincoln Med. Coll. (1904)			79.5
University of Iowa..... (1903)			78.2

FAILED.

University of Vermont..... (1899) **72.3

* Reciprocity, with supplemental examination, 4 subjects.

Failed on previous examination; this was his second examination.

** Third examination.

SURGERY.

1. What is the point of selection for resection of the ribs, and why? 2. Name the conditions requiring, and the usual method of performing, (a) thoracentesis, (b) resection of ribs. 3. A man falls from a chair in a saloon and receives a slight scalp wound. He goes to bed and is found, four hours later, in a state of coma. To what may the coma be due, and how would you treat the patient? 4. What are the symptoms of stone in the bladder? 5. What complication is apt to result from a fracture of the tibia and fibula immediately below the knee joint, with backward displacement of the proximal fragments? Treat the fracture. 6. Name the different varieties of urethral stricture, and describe the methods of treating them. 7. How would you treat a septic infection of an extremity? 8. State what you consider, giving your reasons, to be the most suitable suture material for (a) intestinal anastomosis, (b) uniting the peritoneum, (c) uniting the muscular layers of the abdominal wall, (d) closing the skin. 9. What general principles must be followed in treating a fracture occurring at or near joints? 10. What is a sprained ankle? Give treatment. 11. What precautions should be observed in producing general anesthesia with (a) chloroform, (b) ether; and local anesthesia with cocaine?

BACTERIOLOGY.

1. What bacteria are associated with inflammation and suppuration? 2. What are Koch's postulates? 3. Give in detail a method of staining for the tubercle bacillus. 4. Is the Widal reaction always conclusive? Describe the method of producing it. 5. To what uses has his ordinary work can a general practitioner put a microscope?

ANATOMY.

1. Describe the first, ninth, tenth and eleventh dorsal vertebrae. 2. Draw a diagram of and describe the ulna. 3. Mention the muscles of the forearm, and give origin and insertion of any two of them. 4. Describe the course of the femoral artery, and its relation to the iliac vein. 5. Give nerve and blood supply of the pancreas. 6. Describe the canal of Wirsung. 8. Describe the hepatic duct. 9. Describe the larynx. 10. Describe Meckel's ganglion.

DISEASES OF WOMEN.

1. Give cause, diagnosis and treatment of "erosion of the cervix." 2. Give differential treatment of extruterine pregnancy and intrauterine fibroid. 3. Give treatment of membranous dysmenorrhea. 4. Give diagnosis and treatment of gonorrhea. 5. Describe infantile uterus. Give treatment.

EYE AND EAR.

1. Define blepharitis, epiphora, photophobia, pterygium and hyperopia. 2. Sketch cross-section of eyeball in antero-posterior plane. Name and show relation of parts. 3. Define dacryocystitis. Give treatment of an acute case. 4. Outline case of traumatic orbital abscess. Give preventive treatment. 5. Name symptoms which would justify a mastoid operation.

SKIN AND VENEREAL.

1. How would you treat a case of acute gonorrhea, and how would you positively diagnose gonorrhea microscopically? 2. Describe and treat lupus vulgaris. 3. Differentiate eczema and seborrhea of the scalp, and treat the former. 4. Describe primary chancre. How would you treat a patient who has one? 5. Name four (4) contagious diseases that have diagnostic skin eruptions. Describe the eruptions of each.

PHYSIOLOGY.

1. Describe chyme and chyle. 2. Give the normal constituents, reaction and specific gravity of urine. 3. Whence do bones derive their nourishment? 4. Give the mechanism of respiration and its purpose. 5. Give examples of morbid reflex action. 6. Describe the temporary and permanent sets of teeth. 7. What are the functions of the lungs? Describe their action. 8. How is animal heat produced. 9. Describe the physiology of vision. 10. Name the active principles of the digestive secretions, and describe how each affects the food.

GONORRHEA.

1. Describe the internal organs of generation and their anatomic relations, giving blood and nerve supply of each. 2. Describe a transverse presentation, giving diagnosis and your management of the same in a given case. 3. Give symptoms indicating death of child in utero. 4. Give usual relative time of the different stages of labor. 5. Give the indications of syphilis in the new born child. 6. How would you manage a prolapsed funus? What are the dan-

gers? 7. Define uterine inertia, and give its immediate and remote significance. Give treatment. 8. Describe in full your management of the third stage of labor. 9. When would you use forceps with head in the upper strait? Describe manner of so using them. 10. Give causes of lacerated cervix, also time and manner of treatment.

GENERAL PATHOLOGY.

1. How should sputum be examined when tuberculous infection is suspected? 2. What is a giant cell? 3. What degenerative changes occur in arteries? 4. Give the causes of edema. 5. Where do we generally find myofibrillates?

THERAPEUTICS AND REGULAR PRACTICE.

1. How do borax and boric acid differ chemically and therapeutically? 2. How would you use croton oil? 3. Describe the proper method of giving hypodermic injections. 4. What do you know of the uses and effects of scopolamine? 5. Mention a soluble and insoluble salt of lead, and tell how and for what purpose they are used in medicine. 6. Name one important complication, one sequel, and give ordinary care limit of typhoid fever. 7. How should apoplexy from cerebral hemorrhage be treated? 8. Define hysteria. 9. Differentiate abscess and cancer of liver. 10. What do you understand neurasthenia to be?

ECLECTIC MATERIA MEDICA, THERAPEUTICS AND PRACTICE.

1. In what pathologic conditions is camphor used? Give dose used internally. 2. Give some of the therapeutic uses of cuprum sulphate, also the doses. 3. Name and give dose of a hydragogue; also of a chologogue. 4. Name some of the test remedies to control vomiting, and give dose of each. 5. For what is apomorphine used? Dose of same. 6. Give symptoms and treatment of a case of malarial fever. 7. Write a prescription for insomnia. 8. Give the dose of (a) nitroglycerin, (b) atropin, (c) potassium iodid. 9. Give symptoms and antidotes in opium poisoning. 10. Give differential diagnosis between alcoholism and apoplexy.

CHEMISTRY.

1. What do you understand by chemical action? Give examples. 2. Distinguish between synthetic and analytic reactions. 3. What group of elements (radicals) is characteristic of all hydrates, carbonates, urates, sulphates? 4. What are alkaloids? Name the essential alkaloids of opium. 5. Give chemical name and formula of lunar caustic, caustic potash, fire damp. 6. Give a chemical test for pus and mucus in urine. 7. What sediments are soluble (a) when heated in superheated urine, (b) with acetic acid, (c) with hydrochloric acid? 8. What causes hardness in well water? 9. What chemical is in rubine, rat poison and poison (B) paper? What are the best antidotes for poisoning by it, and how may the antidotes be most conveniently prepared? 10. What is iye chemically considered? What antidotes for poisoning by it?

HOMOEOPATHIC THERAPEUTICS.

1. How do you treat pneumonia? Give remedies used in each stage. 2. Outline your treatment of membranous croup. Give indications for each remedy. 3. Give the names and indications for three prominent remedies in the treatment of diarrhea. 4. Differentiate between belladonna, china, and secale in uterine hemorrhage. 5. Give characteristic symptoms calling for rhus in rheumatism; also in typhoid. 6. Name two remedies (giving indications for their use) in nervous affections. 7. Outline your treatment of purpural eclampsia, giving dose and potency of remedies used. 8. Differentiate nux vom, Ipecacodum and ipecac in stomach troubles. 9. Describe a case fully in which you would use sulphur. 10. Differentiate arsenicum, hepar sulphur and silica in pus affections.

MEDICAL JURISPRUDENCE.

1. What are the powers of the coroner? 2. Of what importance is the gaping of the wound? 3. What are the postmortem appearances peculiar to death by asphyxia? 4. Differentiate rigor mortis from the rigidity of hysteria, cataplexy. 5. When called as a medical witness, (a) must a physician obey the summons of the court? (b) must he be satisfied with the fee of an ordinary witness? or (c) when may he charge more for his services? and (d) why?

Virginia December Report.—Dr. R. S. Martin, secretary of the Medical Examining Board of Virginia, reports the written and oral examination held at Richmond, Dec. 12-15, 1905. The percentage required to pass was 75. The total number of candidates examined was 125, of whom 40 passed, including 6 who were licensed by reciprocity; 17 failed. Sixty-seven undergraduates took a partial examination. One candidate handed in no paper. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Hospital Coll. of Med.	(1903) 78; (1905) 76		
University of Virginia.	(1887) 95; (1900) 86; (1901) 86; (1904) 78, 80, 82, 85; (1905) 79		
College of P. and S., New York.	(1883) 75		
Pulte Med. Coll.	(1905) 75		
Leonard Med. Coll.	(1904) 75, 75; (1905) 76		
Columbian University.	(1891) 80		
Medical College of Virginia.	(1905) 75, 76, 77		
Medical College of Ohio.	(1867) 75		
University of Pennsylvania.	(1902) 86; (1903) 85		
University Coll. of Med.	(1891) 80; (1905) 76, 76, 79		
National University, Washington.	(1903) 81		
Drumright Homeo. Med. Coll.	(1897) 75		
University of Maryland.	(1905) 77		
George Washington University.	(1886) 75; (1905) 85		
Maryland Med. Coll.	(1905) 75

Jefferson Med. Coll.	(1891)		59.9

Medical Organization

What Can the County Society Do?

XII. STOP TESTIMONIAL GIVING.

At one of the "business" meetings during the year the subject of discussion may with great profit be "testimonials." Starting with the text that the giving of testimonials for any article employed therapeutically is reprehensible, the subject in its various aspects can be freely discussed. Every effort should be made to utilize the occasion to secure an agreement among all the doctors in the county that no testimonials whatever will hereafter be given. An appropriate proceeding would be, after proper notice, to bring the subject up in the form of a resolution declaring the society's adhesion to the pronouncement on this subject of the "Principles of Ethics" of the American Medical Association. Possibly in some societies this might best be done at the same meeting at which there is full consideration of the proprietary medicine evil.

XIII. EXPOSE SWINDLING.

At an early meeting to which some of the laity are invited the two articles by Mark Sullivan in the *Ladies' Home Journal* for January, 1906, should be read and submitted for general discussion. The revelations of swindling in the patent-medicine traffic are therein so dramatically and so convincingly laid bare that much good to the community is sure to follow their general public discussion. As before observed, the joint meeting with the laity is one of the very best methods of popular instruction in matters pertaining to the public health. Every county society can readily adopt the method, and these timely topics of discussion furnish admirable opportunity to arouse public interest in the establishment of the custom.

Businesslike Methods Desirable.

The conscientious physician must have due regard for the commercial side of his profession, because a poor physician, one who can not provide himself with the proper and necessary equipment, one who can not keep in touch with medical progress, is a dangerous man; and in order to equip himself properly and to keep abreast of the times he must make a satisfactory income. He should keep his accounts accurately and see that his bills are rendered promptly and every effort made to collect them, save in cases of destitution. People in general have more respect for a man who manages his affairs in a businesslike way than for one who is careless and shiftless. There is no more reason why the physician should give his patients a year or more credit, provided they are able to pay, than there is for the grocer or the butcher to do so. "Short

accounts make long friends." A course on business methods would be a very good thing for every county medical society to arrange, and undoubtedly much betterment would result; betterment not only to the physicians themselves, but to their patients and the community generally. With a harmonious profession and an active county medical society in which are all reputable physicians of the county, there will be fewer well-to-do families getting their medical attendance free, year in and year out. While commercialism, as such, has no part in the professional life of a physician, common sense or "horse sense" has, and it should be applied literally to the physician's business methods.

Benefits in Attending Medical Society Meetings.

The *Southern Practitioner* says editorially:

"Take a careful look at the membership of the American Medical Association during its entire existence for many years or of any state or local organization, and you will find enrolled therein the ablest, the most successful, the most prominent medical men of the particular time under consideration. Our busiest members have found time to participate in the meetings, if not every year, at least a great proportion of the time. Occasionally we have made overtures to professional men in regard to participating in society work, and have been met with the statement, 'We are too busy,' 'Could not spare the time;' yet a careful observation has forced the conclusion that such would have done better if they had never opened a medical book, and had devoted their time and talents to some other vocation. Unquestionably times do occur that professional or other duties will prevent attendance on a given meeting of a local or state society, and all can not attend the annual meetings of the national association; yet, if each member of the profession will but endeavor to participate in as many meetings of his local society, and occasionally attend a meeting of his state organization, he will find that the time so spent will be of more intrinsic value in the end than double the time spent in any other duty—yes, we regard this as a duty incumbent on any practitioner acting for the best interests of himself and those dependent on him for professional services. This may be regarded as a strong statement, yet it is the result of careful observation during more than forty years of professional life, and we know will be substantiated by the leading medical men of this and all other enlightened and civilized countries.

"Much has been said about the benefits and advantages of organization. Its results are seen everywhere, and to no body of men is it so important, so necessary and essential, as it is to the members of the medical profession. Except in occasional instances of consultation, their very work leads them to segregation and isolation. A daily duty of making visits as a duty renders to some extent social visiting irksome; and even though one is an omnivorous reader of standard and periodical literature, he is apt to get into a groove, be limited in his views and resources, narrow in his observation—all of which is overcome by an occasional meeting with a collective number of others, some his inferiors, others his peers, and possibly a few his superiors in like work. By such association he adds his experience to that of others, and has the far wider experience of others added to his. Not all at one time, but a little at this meeting, more at another, and when he has established the habit—we are all more or less creatures of habit, of becoming a regular attendant at even local society meetings—it is astonishing how his entire methods, measures, manners, and life in all its technical details are broadened, advanced, and materially increased.

"By organization and regular meetings personal jealousies, petty bickerings, slanderous and scurrilous backbitings disappear and are supplanted by a broad and liberal ambition and emulation as to who can excel and who can add the more to the sum of professional knowledge, skill, and correct technic. Nor is it alone from the papers, essays, and discourses thereon that we can and do derive a national benefit. Some of the most practical and valuable ideas and suggestions ever received have been obtained in the personal conversation with other medical men in attendance on a meeting. While many valuable ideas and thoughts have resulted from careful attention to the regular program, yet some of far more value have been obtained in the social intercourse and conversation on assembling before the meeting as called to order and after its close."

Arizona.

SANTA CRUZ COUNTY MEDICAL SOCIETY.—At the annual election of officers of the Santa Cruz County Medical Society, held at Nogales, February 1, the following was the result: President, Dr. Adolphus H. Noon; vice-president, Dr. Harry W. Purdy; secretary and treasurer, Dr. Albert L. Gustetter; delegate to Arizona Medical Association, Dr. Ray Ferguson, and censor, Dr. Nicholas K. Noon, all of Nogales. This society was recently organized on the standard plan and begins its work with good promise for the future.

California.

TEHAMA COUNTY MEDICAL SOCIETY.—Physicians of this county met at Red Bluff, Dec. 6, 1905, and after an address on organization by Dr. Philip Mills Jones, San Francisco, secretary of the state society, organized a county society on the standard plan, electing the following officers: President, Dr. John M. West; vice-president, Dr. Frank J. Bailey, and secretary, Dr. Frank L. Doane, all of Red Bluff.

PIKE COUNTY MEDICAL SOCIETY.—Under the guidance of Dr. Mallie A. Clark, Macon, counselor for the sixth district, a county society on the standard plan was organized at Barnesville, Dec. 19, 1905, with an initial membership of 13, and the following officers: Dr. John C. Beauchamp, Williamson, president; Dr. John A. Corry, Barnesville, vice-president; Dr. M. M. Beal, Zebulon, secretary and treasurer; and Drs. George M. McDowell, Molena; John M. Anderson, Barnesville, and William M. Aycock, Williamson, censors.

Connecticut.

Bristol Medical Society.—The physicians of Forrestville, Plainville and Terryville have organized a medical society.

Georgia.

TALIAFERRO COUNTY MEDICAL ASSOCIATION.—Physicians of the county met at Crawfordville February 6, and with the aid of Dr. W. W. Pilcher, Warrenton, counselor for the tenth district, organized a county medical association, with the following officers: President, Dr. Arthur C. Davidson, Sharon; vice-president, Dr. John A. Rhodes, Crawfordville; secretary, Dr. A. H. Beazley, and censors, Drs. Lawrence R. Brown, Sharon; Power, and John A. Rhodes, Crawfordville.

SPALDING COUNTY MEDICAL SOCIETY.—Physicians of the county met at Griffin, Dec. 8, 1905, and organized a county society on the standard plan with the following officers: President, Dr. Nicholas B. Drevry, Griffin; vice-president, Dr. William M. Byne, Zetella; secretary, Dr. Joseph M. Thomas, Griffin, and treasurer, Dr. Thomas J. Collier, Griffin.

MCDUFFIE COUNTY MEDICAL SOCIETY.—On January 16 the physicians of the county met with Dr. William Z. Holliday, Augusta, president of the Medical Association of Georgia, and Dr. W. W. Pilcher, Warrenton, counselor for the tenth district, at Thomson, and organized a county society on the standard plan. The constitution and by-laws approved by the state association were adopted, and the following officers elected: Dr. Edward S. Harrison, Thomson, president; Dr. Sterling R. Gibson, Thomson, vice-president; Dr. B. F. Riley, Jr., Thomson, secretary and treasurer; Drs. F. N. Ware, Thomson, and Aaron J. Mathews, Thomson, and Z. Daniel Story, Winfield, censors, and Dr. Z. Daniel Story, Winfield, delegate to the state association. Every physician in the county has joined the society.

Kentucky.

NICHOLAS COUNTY MEDICAL ASSOCIATION.—The physicians of the county met in Carlisle, January 26, for the purpose of reorganizing the county association. Dr. Robert J. R. Tilton, Carlisle, was elected president; Dr. Oliver S. Kash, Moorefield, vice-president, and Dr. George B. Spencer, Carlisle, secretary and treasurer.

Louisiana.

FRANKLIN PARISH MEDICAL SOCIETY.—The physicians of Franklin Parish met January 19 at Jonesboro and organized a medical society in affiliation with the Louisiana State Medical Society, with the following officers: Dr. Mallory B. Culpepper, Hood's Mill, president; Dr. George E. Cannon, Jonesboro, vice-president; Dr. J. A. Gaar, Jonesboro, secretary; Dr. Isaac M. George, Jonesboro, treasurer.

Maine.

MEDICAL ASSOCIATION OF KENNEBEC COUNTY.—At the regular meeting of this association, held in Waterville, January 24, Dr. Seth C. Gordon, Portland, delivered an address on organization, giving the history of the work already done in that line through the efforts of the American Medical Association.

Michigan.

ALLEGAN COUNTY MEDICAL ASSOCIATION.—This association has been consolidated with the Kalamazoo Academy of Medicine.

Missouri.

LAWRENCE COUNTY MEDICAL SOCIETY.—Twelve physicians of this county met at Mount Vernon recently and organized a county society, adopting the standard constitution and applying for a charter to the Missouri State Medical Association. The following officers were elected: President, Dr. James A. Harris, Mount Vernon; vice-president, Dr. F. S. Stevenson, Aurora; treasurer, Dr. John P. Andrews, Marionville; secretary, Dr. Charles A. Moore, Aurora, and censors, Dr. Alphonso H. Madry, Aurora; Charles W. Shelton, Mount Vernon, and John B. Fleming, Aurora.

New Jersey.

MERCER COUNTY MEDICAL SOCIETY.—At a meeting of this society in Trenton, January 9, a complete report was made by the committee which had had in charge the consideration of the reorganization of the society on the standard plan.

North Dakota.

TRAIL-STEEL COUNTY MEDICAL SOCIETY.—The physicians of Trail and Steele counties met in Mayville, January 31, and organized a society on the standard plan with the following officers: Dr. Kristian A. Wadel, Portland, president; Dr. George McIntyre, Mayville, vice-president; Dr. Edward C. Haagenensen, Hillsboro, secretary, and Dr. Archibald N. Currie, Hatton, treasurer.

South Carolina.

FOURTH DISTRICT MEDICAL SOCIETY.—Physicians of the fourth district met in Greenville, February 5, and organized a district society on the standard plan. Dr. J. Wilkinson Jervey, Greenville, counselor for the fourth district, was elected chairman, and Dr. Edgar A. Hines, Seneca, secretary.

Texas.

SMITH COUNTY MEDICAL SOCIETY.—The medical society of this county has changed its method of work, and on January 9 began a series of monthly postgraduate courses in medicine to which every physician in the county was invited. A program of clinical work for the day was arranged, cases and demonstrations being given in tuberculosis, heart diseases, diseases of the kidneys and diseases of the skin. This movement is a gratifying evidence of the beneficial results of the work done in Texas by Dr. McCormack in the fall.

Utah.

CACHE VALLEY MEDICAL ASSOCIATION.—A number of physicians from the Cache valley, including some from Preston and Franklin, Idaho, met in Logan City, January 24, and organized a medical association in uniformity with the state association. The following officers were elected: President, Dr. Russell J. Smith, Smithfield; vice-president, Dr. G. W. States, Franklin; secretary and treasurer, Dr. Heber K. Merrill, Logan, and program committee, Dr. R. J. Smith, Smithfield; Dr. Albert H. Cantril, Hyrum, and Dr. Emery, Preston.

Virginia.

RAPPAHANNOCK VALLEY MEDICAL SOCIETY.—The physicians of Fredericksburg have reorganized this society and have elected Dr. Joseph N. Barney, president, and Dr. W. Jeffries Chouwing, secretary and treasurer. The first meeting of the reorganized society was held January 5.

Society Proceedings

JEFFERSON COUNTY MEDICAL SOCIETY.

Regular Semi-monthly Meeting, held at Birmingham, Ala., Jan. 22, 1906.

The Gospel of Patent Medicines.

Dr. J. ROSS SNYDER read a paper with the above title. He said that the medical profession had been accused by some ministers of harboring skepticism and infidelity. After denying the breadth of this charge, Dr. Snyder suggested that the attitude of many leading ministers toward patent medicines was so inconsistent with high standards of morality that physicians

in turn might well speak skeptically of the ministers. Many ministers lend encouragement to patent-medicine frauds, some by testimonials, others by soliciting and publishing advertisements in the religious papers over which they have control.

In a recent issue of the *Alabama Christian Advocate* there were seventy advertisements in all, twenty of which were of patent medicines. In the *Alabama Baptist*, out of fifty-two advertisements twenty-two were of patent medicines. Dr. Snyder gave the names of the medicines advertised in both papers, but did not discuss in detail all of them. He thought this not necessary, for the fraud contained in many of the advertisements was too glaring to permit any plea of ignorance by the publishers of the papers. A few of the advertisements, however, he discussed in detail.

The proprietors of Dr. Lord's headache powders had admitted to Dr. Snyder that the preparation contained about two grains of acetanilid to the dose. The deleterious and sometimes fatal effects following the continued use of acetanilid were illustrated. Dr. Snyder suggested that the Alabama State Medical Association ought to father a bill prohibiting the sale of acetanilid except on a physician's prescription.

Physicians can only deal successfully with tumors and cancers by using the knife. "Dr." Bye, however, says he can remove any of these with oils. That any oil, potent enough to take the place of the knife in the removal of tumors and cancers, can be either "balm" or "soothing" is a contradiction striking enough to be ludicrous.

Mrs. Winslow's soothing syrup advertisements found conspicuous space in both papers. The active ingredient in this syrup is opium. The physiologic action of opium, the susceptibility of children to the drug, and the opium habit were discussed. Soothing syrups were characterized as the most damnable of all nostrums.

"Mrs. M. Summers" advertised in one of these religious papers a preparation for the cure of all female troubles. Dr. Snyder showed that back of this advertisement is not a woman, but a pharmaceutical house which manufactures seventeen doubtful preparations. The advertisement is a deception meant to obtain from women their secret conditions, revealed in the belief that they are communicated to one of their own sex.

The "Marvel whirling spray syringe" was cited as another indecent advertisement. If the publishers of the paper do not know that this is sold chiefly as an instrument for preventing conception they are less discerning than a majority of their readers. It requires no stretch of the imagination to trace the downfall of a young girl to too close reading of a religious paper.

Some states and some secular papers prohibit the publication of obscene and indecent advertisements. It is a remarkable comment on Christian churchmen that they are less discriminating on this question of morality. Attention was called by Dr. Snyder to the inconsistency of any paper pleading for the temperance cause and publishing in the same column the advertisement of alcoholic patent medicines.

In reply to a subscriber's criticism of the patent-medicine advertisements in a certain religious paper, one of the editors said in the paper that "there is plenty of good reading in the paper except those who were scenting around for something to object to; the patent-medicine advertisements are only intended for people wanting something of that kind." This editor was compared to a minister who would build a brothel, a saloon and a church under one roof, and who would defend himself by saying that the church was big enough for all good people, and only those "wanting something of that kind" need get into the other two places.

After expressing the hope that the evil of "patent medicines" was becoming generally admitted, the ministers were invited to "come over on the Lord's side."

DISCUSSION.

Dr. THOMAS D. PARKE sustained the general charge and stated that reform along this line had been earnestly urged on the press by the society more than once during the past ten years.

The editors of the two local religious papers had been notified in advance of the topic for discussion, and had been invited to be present. They were accorded the privileges of the floor and were invited to express themselves on the charges preferred.

REV. FRANK W. BARNETT, editor and proprietor of the *Alabama Baptist*, acknowledged a realization of the impropriety of some advertisements carried by his paper, and stated that he was engaged in an investigation looking toward the possibility of discontinuing such, when apprised of the nature of the meeting. He further explained that he found himself bound by a three-year contract to carry many of these advertisements until the expiration of this agreement, and would, when possible, discontinue the advertising of such nostrums as might be proved to be of a harmful character. Going into the methods of advertising agencies, as explained to him through their representatives, he stated that one department had charge of all "patent-medicine" advertising in all religious papers in the southern states; that the refusal of one or more advertisements by one or more papers in a state might nullify the contract for the agency or its representative, and that such arguments were adduced by said representatives as obligations on the papers to continue such advertising *in toto*. He confessed that he had failed to see the fraudulency or impropriety of certain advertisements which Dr. Snyder believed to be self-evident.

REV. J. D. ELLIS, editor of the *Christian Advocate*, corroborated in the main the defensive plea offered by the preceding speaker. He cited one clearly indecent advertisement which had appeared twice in his paper, to be withdrawn, and believed Dr. Snyder should be given due credit for such action, and for the expressed intention of discontinuing some advertisements when found possible.

DR. SNYDER stated his failure to discover reasonable evidence of intention or efforts toward a proper reformation and reiterated his charges.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, Jan. 24, 1906.

The President, DR. CHARLES K. MILLS, in the Chair.

SYMPOSIUM ON THE CARE OF THE INDIGENT INSANE.

Public Care of the Insane.

DR. JOHN B. CHAPIN, of the Pennsylvania Hospital for the Insane, likened the Philadelphia Hospital to an enlargement of the county poorhouses of early days, caring for the sick, poor, paupers, idiots and insane. It was stated that from a general observation the majority of the insane poor were, previous to the insanity, self-supporters, rent-payers, and in a sense indirectly tax-payers. They were, therefore, entitled to relief and care. The first essential in their care was said to be an absolute divorcement of the insane from an almshouse with its associations and traditions. The new hospital should be in the country. There should be a qualified medical director, clothed with ample power, possessing a reasonable tenure of office and in no way subject to a so-called warden, who would soon or late stand for some political organization. Among some of the results realized by the chronic class of patients would be the formation of orderly habits of living and occupation afforded by the opportunities of a farm and a large community, decided improvement in the mental condition of the whole number and the restoration of many to their families.

Whether this work should be undertaken by the city or state was considered immaterial, provided it was well done. If undertaken by the state there will be a reasonable guaranty that a higher standard of care would be maintained and the institution be free from the demoralizing influences of politics. Accommodation should be provided for at least 1,800 patients, together with the necessary officers and employees, and a scheme agreed on to meet the inevitable annual permanent increment. The plan of erecting plain, substantial blocks, or detached buildings, supplemental to an administration building, which

could be added to from time to time, furnishes a suggestion for the scheme which is now proposed. The detached blocks furnish extraordinary facilities for classification of special cases and reduces the danger of destruction by fire to a minimum. Any plan presented should permit of additions and expansion as necessary.

Assuming the removal to the country of the pauper population, Dr. Chapin believes there should be provided on the present site a hospital for the reception of emergency cases, acute cases of delirium from any cause and persons arrested requiring temporary detention on the sudden outbreak of insanity. Many such cases, he believes, would be discharged without transfer to the colony. This institution should be a hospital in name and fact, equipped for the best hospital care of acute cases.

The adoption of some such plan as outlined, Dr. Chapin believes the only one which will solve the present problem of the disposition of the large number of chronic insane persons now in the Philadelphia Hospital. Each patient should have a proper allotment of cubic and superficial space, and a dietary should be established to meet the wants of the able-bodied as well as the sick and feeble. There should be organized a medical service of a high standard for the emergency wards. This, in Dr. Chapin's opinion, the medical profession has a right to demand as citizens and sympathizers with a distress that may afflict any one in the community. If this is well done he does not think tax-payers will question the expenditure. To do less than is proposed he believes will result in the gradual degeneration of the whole service, as has been shown in every municipality where the attempt has been made to care for the insane poor apart from state supervision and control.

State Care of the Insane in New York.

DR. FREDERICK PETERSON, ex-president of the New York Commission in Lunacy, in reading this paper said that it was a singular circumstance that a stranger should speak to Philadelphians on the humane care and treatment of the insane, for Philadelphia had been the first city in the Union to preach the gospel of sickness for these unfortunates and the first to practice the doctrine. More than 150 years ago Philadelphia established a hospital for the insane, which was a long step in advance of that period. Dr. Rush, of Philadelphia, was the Pinel of America. He abolished whipping as a remedial measure for insanity and discarded manacles and chains.

Dr. Peterson reviewed the progress of the insanity legislation in the State of New York, the first step of which was taken fifty years subsequent to the establishment of a hospital for mental disorders in Philadelphia. By 1896 all of the indigent insane of the State of New York had been placed under state care. The fourteen state hospitals and the twenty-three private retreats for the insane are all under the jurisdiction of the State Commission in Lunacy, consisting of a physician, a lawyer and a business man. These private retreats are supervised and inspected, and licenses may be revoked on failure to comply with the regulations of the commission. This body has not only supervision over the state hospitals, but the entire management of the expenditures for the maintenance of the patients and the construction of new buildings. The old idea of separate provision for the acute and chronic patients was long ago abandoned.

A summary was given of changes in contrast to the methods employed in the county management. Among these were the establishment of training schools for nurses in all of the state hospitals, a central pathologic institute or school of psychiatry at Ward's Island in the New York City asylums, to which all the assistant physicians from the various hospitals of the state go for instruction in the latest scientific methods of study and treatment of the insane. This is under the directorship of Dr. Adolf Meyer. Most of the hospitals have staffs of consulting physicians from neighboring cities. A woman physician, a salaried dentist and an oculist are required at each hospital. Each hospital is thoroughly equipped with everything needed in medical and surgical instruments and appliances. Emergency commitments now in force give speedy access to hospital care. Restraint by means of straps, etc., has been almost abandoned, and some wards have unbarred windows and doors. Occupa-

tions for the patients have multiplied and the work of the able-bodied in shops, gardens, fields have monetary value. Wards and rooms have been made attractive and religious services are held by salaried chaplains. Special tuberculosis hospitals have been constructed at several of the county asylums, and several of the hospitals have small colonies at a distance for the care of convalescent patients in change of air and scene.

New York State has appropriated \$300,000 to construct a psychopathic hospital on Manhattan Island to act as a distributing center for the insane of all classes. It was urged that every great city should have emergency pavilions in connection with the hospitals to which patients supposed to be insane can be at once taken, not only for observation, custody and diagnosis, but for immediate treatment.

DISCUSSION.

DR. W. M. L. COPLIN thought that no large city could properly care for the insane and the indigent not insane in its corporate limits on account of the value of the ground and because of the higher cost of maintenance than in the country districts. The general influence of the outlying districts, he felt, was better than that of the city. He favored the establishment of detention or observation wards similar to those in New York for the treatment of cases curable within a reasonable time and for cases in which careful study might offer better methods of treatment. Such quarters should accommodate from 200 to 300 patients and should be exceedingly elastic to prevent possibility of overcrowding. They should be well officered with eight or ten volunteers, and in addition men of experience and competent to teach the volunteers. Above these there should be a consulting or directing staff, composed of men of eminence. He would have the tuberculosis cases treated separately from those not tuberculous. He regarded the present unfortunate condition of the insane poor of Philadelphia largely the result of an increase in numbers, which had exceeded the growth of facilities, and said that it was difficult to impress on governing bodies who distribute the public funds the fact of the increase of numbers of the insane poor and the advances made in the treatment of insanity.

The question of lured help was also considered. Intelligent help would naturally work in those institutions in which the environment was in accord with their own individuality, and the city institution would probably receive what was left. The point to be realized by the medical profession was that law-making and appropriating bodies would give that which was desired if the matter were kept before them and the urgency shown. It was well to drive home to the people the necessity of such reforms and have their sympathy.

DR. F. X. DERGUM said that specific and practicable plans should be outlined, and believed that the psychopathic hospital which should take the place of detention wards was a necessity and a feasibility. The stigma of a commitment also by this means would be obviated. He would favor caring for the insane of the city at Norristown, where there are ample grounds for buildings; and, because of its ready access from Philadelphia, patients could be readily transferred from the psychopathic hospital. He expressed his hearty accord with the idea of convalescent wards and colonies if they be proven practicable. He thought all were painfully impressed with the difference in the care of the insane of Philadelphia and that of New York, and felt that it was largely dependent on the profession to make known the wants of the insane and to maintain the agitation until something definite shall be achieved. He realized the difficulty of securing the highest-class attendants at the almshouse, but thought it might be overcome by the establishment of training schools. He would favor the establishment of a training school for men similar to that in New York who would take charge of the male wards in the hospital and in the psychopathic department. The pupils should receive little or no pay and leave at the end of a definite time with a definite earning power. To get along with the no-restraint method there would be a larger number of attendants and better paid attendants required. He agreed with Dr. Coplin that the authorities would grant the improvements asked for by the medical profession.

DR. CHARLES W. BURR said that he knew of no new argu-

ment for a change of conditions at Blockley, that it was a perfectly well-known fact that the insane department of the Philadelphia Hospital and, indeed, of Blockley itself, was not an honor to the city of Philadelphia. It was also known, or ought to be known, that it was the fault of no one but the citizens of Philadelphia. They were blameworthy, first, because they do not like to spend money, and, second, because until very recently they were perfectly willing to be robbed, so long as the money was not taken out of their individual pockets. The one way to straighten out the difficulty was to take the care of the insane poor entirely out of the hands of the city. He favored the establishment of the psychopathic ward in which cases of acute mental disease could be taken at once.

DR. WILLIAM G. SPILLER said that no one could doubt the needs of Blockley, that until within the last few weeks patients had been sleeping on the floors. The subject which Dr. Coplin had brought before the public was not a new one. He recalled the hopefulness entertained by many of the staff for a few years previous when looking about for a site, which efforts, however, had fallen into the background, and it was not surprising that a pessimistic view had overtaken some. Personally he was delighted to know of the hopeful outlook held by Dr. Coplin. In listening to Dr. Peterson's paper he felt the difference existing between New York and Pennsylvania in the care of the insane. Reference was made to the high class of work done by Dr. Meyer on Ward's Island. He asked that Dr. Peterson would describe the non-restraint system. It had been his misfortune to have a patient jump out of a window; this, he felt, was also likely to occur among those slightly insane.

DR. WILLIAM PICKETT believed that the immense advance in New York State in the care of the insane was largely due to the fearless and energetic work of Dr. Peterson. During the ten years of Dr. Pickett's association with Blockley he had seen several plans developed, all of which had failed. The present movement he believed would succeed under the management of Dr. Coplin. He felt strongly that it was an ordinary commonsense proposition that Philadelphia should have an emergency ward for the insane. In 100 admissions to the insane wards he had found that thirty patients recovered in two months or less, twenty-four in six weeks or less and that about sixteen recovered within a month. All of the trouble, expense and stigma—if there be such—of a commitment could be thus saved by the emergency ward or hospital. Such a ward he believed in addition to lessening the number of chronic insane in the state hospitals, would diminish the tendency to recurrence of insanity, and above all, would save from an insane asylum many of the cases of puerperal insanity, and confusional insanity in terminal Bright's disease, pneumonia and other physical disorders. In such a psychopathic hospital there should be accommodations for at least 300 patients.

DR. ALFRED GORNON emphasized strongly the necessity of first instructing the general practitioner in the psychiatry. Should the hospital for the insane be removed from the city, he thought there would be removed the practical means of giving this instruction, and that the future general practitioner would know still less than is known at present of the science and treatment of insanity. He said that in France the study of insanity was made one of the branches in the general curriculum, and that there the general practitioner was able to talk with the laity in an intelligent manner if the necessity arose. He believed that the general hospitals should have a special or psychopathic ward for receiving patients who in the course of pneumonia or other infectious disease might develop delirium. Regarding the insane department of the hospital he would suggest that the staff of alienists take full charge of it, each member of which staff should give at least six months attendance. In addition to this a large number of resident physicians should be appointed. He would place the superintendency in the hands of a layman who would work under the absolute direction of the staff. The psychopathic ward should also be under the full charge of the staff of alienists, for cases even slightly confused at the beginning should be under the care of eminent men.

DR. HAWK thought that the state should have immediate care of the city insane. He said that those in charge at

Blockley were greatly handicapped by insufficient funds, and that for the more than 1,800 patients there was a totally inadequate number of physicians. The work of the internes as alienists he regarded as practically useless. At times 15 to 20 cases were admitted in a day. Only within the last month had the full quota of assistants been allowed by councils. Last year there had been paroled and discharged over 12 per cent. of the whole number of patients under treatment. In the majority discharged as recovered it was meant that they were possibly as well as they had been for some time prior. In 4 or 5 per cent. there was absolute recovery. The death rate had been 13 per cent. plus. This was due to the fact that many of the cases are of senile dementia with a large proportion between the ages of 70 and 100 years. Such cases had been transferred to the insane department because there was no other means to take care of them. Dr. Hawk thought the average for other cases would compare favorably with those of many of the New York asylums, and said that every endeavor had been made to keep the standard at Blockley high, but that the means had been entirely inadequate for the purposes desired.

Dr. A. R. MOULTON feared the idea would go out that the medical work at Blockley was not well done. He had, however, had opportunity for observing the work at Blockley and could say that the medical work in the insane department was most excellently done, and this was emphasized by the fact of the very large number of patients and the small number of medical attendants. He felt it a duty, as it was also a pleasure, to state that Dr. Hawk had done most excellent work in the Philadelphia Hospital.

Dr. WILLIAM S. WADSWORTH referred to the housing of the insane, pointing out that all could not be housed in the same manner; some could not be put into tents; the working insane should not be housed with the feeble bodied, nor the maniacal with those only temporarily insane. Tents were regarded as undesirable because of the difficulty of keeping them clean. He favored the use of pavilions with the buildings running north and south and placed sufficiently far apart that each would get the east and the west sunlight on the sides of the buildings. There should be connection with the main hospital and as well the ability to isolate any ward at a moment's notice.

The matter of occupation he regarded of extreme importance. There should be something for them to do which would abstract that moral and mental tension which was their destruction. Without a due regard to this element the subject was only partially covered. As medical men, he thought the profession was prone to think principally of the sick insane. There should be something to keep the patient from thinking of himself and so sitting in the darkness of their own minds.

Dr. PETERSON approved of Dr. Wadsworth's suggestions of occupation for the patients and said that the colony system included this. He thought the effort in Philadelphia should be to establish the psychopathic hospital in the city for emergency cases and then, as soon as possible get all the other insane into the country. He suggested that the passage of a law providing for the maintenance and equipment of such an institution on condition that Philadelphia furnish the land and erect the building might be helpful in the project. In New York such a law had been passed in securing their psychopathic hospital.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Arteriosclerosis.

Arteriosclerosis, according to Sir James Barr, in the *British Medical Journal*, is a disease which causes the death of more men in the prime of life and vigor of manhood than any other. The etiologic factors which enter into the cause of this disease are lead, alcohol, excessive nitrogenous foods, age, sex (being more common in men), physical strain, which is a potent factor

in causing high arterial tension and cardiac hypertrophy, leading to early degeneration, as shown in athletes and in laborers. Cold is also regarded by the author as an agent which raises the general blood pressure sufficiently high to produce general arteriosclerosis by long contraction of the superficial vessels and their vasa vasorum. Worry, anxiety and all forms of mental strain are also powerful factors in the production of this condition. He speaks of Americans as being more liable to this disease than natives of other countries, stating that at the age of 60 the majority of Americans are old. In the treatment of this disease the first and important thing to be considered is diet. Too much nitrogenous food should not be consumed. In this connection he refers to the work of Professor Cliftenden on the physiologic economy in nutrition. Although he recommends diet of low proteid value for healthy adults and for those suffering from arteriosclerosis, for growing individuals whose tissues are not fully developed a more liberal allowance of nitrogenous substance should be given. Not only should the amount of food be considered, but the mastication should be slow and the food should be thoroughly divided. A good rule which is laid down in this respect is never to eat until you have an appetite, then to eat slowly, to masticate thoroughly, and never to eat to repletion. Exercise should be prescribed to suit the different individuals, according to age and physical development.

Regarding the administration of medicines, he makes the statement that there are two classes of drugs which he never, or very seldom, prescribes, namely, digestive agents and hypnotics, for if a man can not sleep or can not eat there is something wrong with him and he should be treated and not palliated. As in this condition the man eats too much, his digestion fails him, the insomnia depends on high blood pressure, consequently the cause in each instance must be removed rather than the symptoms treated.

The thyroid preparations are spoken of as very useful in the treatment of arteriosclerosis, as it has been shown that they dilate the arteries. Iodin is often more valuable than thyroid extract, as its metabolic effects are attained by a stimulating action on the thyroid gland. The author prefers the tincture of iodine and the syrup of iodine and tannic acid to the more stable iodids. Adrenalin is, as a rule, injurious in arteriosclerosis, but when combined with thyroid extract or iodine it occasionally does good by maintaining arterial tone and stimulating the heart.

THE CITRATES.

The citrates, according to A. E. Wright, have a decidedly decalcifying effect on the blood. At first they lessen the coagulability, but after prolonged use this is increased, and is due, according to Wright, to the fact that the citrates dissolve the lime salts out of the tissues.

THE BENZOATES.

The benzoates have been favored remedies with this writer, especially in that form of arteriosclerosis associated with kidney involvement. Uremic convulsions cease under their free administration, and they are said to convert uric acid into the more solid hippuric acid and to eliminate other purin bodies. Acting similarly to the salicylates, they have a chologogue action.

THE SULPHATES.

The sulphate and the hyposulphite of sodium, sulphate of magnesium and numerous purgative mineral waters have a good effect in clearing out the intestinal tract and in lowering blood pressure.

THE CHLORIDS.

The chlorids should be limited, as they are depressor agents. Calcium chlorid should not be administered unless there be some definite indications for its use, such as a severe hemorrhage or cardiac failure. Sodium chlorid should only be taken by gouty individuals and in limited quantities. As to other depressor agents, the hippurates of ammonium and sodium are recommended. The nitrites are valuable agents in cases of emergencies, but their effects are too rapid to render them desirable for constant use.

Corneal Ulcers.

Lawson, in an abstract in the *Medical Press*, states that corneal ulcers may be relieved by the treatment with quinin.

especially those large ulcers involving the true cornea, and which are not very infectious; marginal ulcers, scalloped and ring ulcers; all infiltrating and infective ulcerations which are not undermining the edges; neuropathic ulcers. He does not recommend quinin in the treatment of the small superficial ulcers, which usually heal readily under simple and less irritating lotions. The form of quinin solution he recommends is the following combination:

R. Quinina sulphatis.....gr. iv [20
Aque dest.3i 30]

M. Sig.: The eye is to be thoroughly drenched with the solution for five minutes by means of an ordinary eyebath, and repeated four or five times a day.

To the foregoing combination the least possible amount of dilute sulphuric acid should be added to dissolve the quinin salt. Atropin should be instilled twice a day and a bandage applied.

Treatment of Cystitis.

Dr. Howard A. Kelly, in the *Dominion Medical Monthly*, states that in the etiology of cystitis the important predisposing factors are localized congestion, traumatism, retention of urine, reduced health. The exciting causes are the various organisms which have been found in this condition. The clinical forms, according to the writer, are the catarrhal, desquamative, ulcerative, granular, papillary and bullous edema. In the treatment of this condition he states that three important factors should be considered: First, a carefully written analysis of the case, including a description of the appearances in the bladder; second, a well-defined course against the disease; third, great patience on the part of the physician and the patient. In the prophylactic treatment he speaks of not only thoroughly sterilizing the catheter before introducing it, but at the same time cleansing the internal meatus. Further, when there is reason to fear cystitis, and always when the catheter is used, it is well to use hexamethylenamin (urotropin) for a few days in from 5 to 10 grain doses three times a day as a prophylactic. He states that cystitis will rarely occur if this precaution be taken.

The systematic treatment includes medicines by the mouth, injections into the bladder, direct topical treatments of the vesicle walls and surgical treatment, including incision of the bladder. The patient should be put to bed, with complete quiet; the diet should be regulated, tonics administered, with the proper regulation of elimination by the bowels, and massage and baths. As to medicines by the mouth, he recommends large quantities of water. Hexamethylenamin (urotropin) in from 5 to 10 grain doses is of great value in the more recent cases, especially when there is a tendency to alkaline changes. When the urine is too acid, potassium citrate is of value. Boric acid is useful when it is desired to render the urine acid. The administration of the fluid extract of cornsilk (*Zea mays*) in teaspoonful doses will not infrequently have an ameliorating effect on the symptoms. Irrigation, however, is the most important means of treatment of this disease. The simple daily cleansing of the bladder is of exceeding benefit, and by this means he speaks of bringing some very rebellious cases to a successful end. He speaks of the surgical treatment of this disease as consisting of minor surgery in some cases, while major surgery must be resorted to in others.

Rheumatism.

The following combinations are recommended by the *Journal of Medicine and Science* for the local treatment of rheumatism:

R. Acidi salicylici5i 4l
Lanolin3v 20]

M. Ft. unguentum. Sig.: Apply locally to the affected joint. Or:

R. Extracti belladonnae.....gr. v [20
Acidi salicylici3v
Sodii salicylatis, aa.....gr. xv 120
Lanolini3iv 15]

M. Ft. unguentum. Sig.: Apply locally. Or:

R. Ichthyoli5i 4l
Lanolini3ii-vi 8 24]

M. Ft. unguentum. Sig.: Apply locally.

Medicolegal

Vermont View of Compounds Containing Alcohol.

The Supreme Court of Vermont says that, in the case of *State vs. Costa*, where the main question was whether the defendant kept a certain "malt extract" to sell for medicinal uses only, or whether he kept it to sell for use as a beverage, the trial court permitted the actual amount of alcohol and of the other ingredients of the extract to be shown, and properly did so, for the character of a liquid containing more than 1 per cent of alcohol may be such that its use as a beverage is impossible, as is the case with some virulent poisons. The mere fact that a liquid can be and is swallowed does not make it a beverage. So it must be said, in the case of extracts, tinctures, essences and compounds having a legitimate use for medicinal, culinary or toilet purposes, that the mere presence, as a solvent, preservative or otherwise, of more than the proportion of alcohol named in the statute, does not make the preparation one to which the statute applies. In respect to such articles the inquiry is not simply whether they contain more than 1 per cent. of alcohol, but there is the further inquiry whether or not the articles are sold to be used as a beverage. In respect to the sale of such preparations the intent governs. If there is no intent to sell these preparations for other than legitimate uses there is no offense. If, however, a preparation is capable of being used as a beverage, and is sold or kept for sale with the purpose, intent or understanding that it is to be used as a beverage, then, if it contains more than 1 per cent. of alcohol, an offense is committed.

Injurious Substances in Bottles—Fear of Death.

The Supreme Court of Georgia holds, in the case of *Watson vs. Augusta Brewing Company*, that a manufacturer who makes and bottles for public consumption a beverage represented to be harmless and refreshing is under a legal duty not negligently to allow a foreign substance which is injurious to the human stomach, such as bits of broken glass, to be present in a bottle of the beverage when it is placed on sale; and one who, relying on this obligation and without negligence on his own part, swallows several pieces of glass while drinking the beverage from a bottle, may recover from the manufacturer for injuries sustained in consequence. The court says that the case of *Blood Balm Co. vs. Cooper*, 83 Ga., 457, while differing somewhat as to its facts, furnishes strong reasons to support the principle announced. The composition of patent or proprietary medicines is usually shrouded in mystery, and it is generally understood that many such remedies contain ingredients which, if taken in sufficient quantities, will produce injurious results on the person taking them. If, then, one who buys a patent medicine may rely on the obligation of the manufacturer not to place therein ingredients which, if taken in the prescribed doses, will injure his health, certainly the purchaser of an alleged harmless and refreshing beverage should have the right to rest secure in the assumption that he will not be fed on broken glass. Moreover, the duty not negligently to injure is due by the manufacturer in a case of the particular character of the one under consideration, not merely to the dealer to whom he sells his product, but to the general public for whom his wares are intended.

A somewhat peculiar ground of demurrer, the court further says, was one advanced in this case which sought to place on the plaintiff the burden of showing "the size and kind of glass" that he swallowed. Courts have gone far in requiring particularity of pleading, but this court is not aware of any rule which would require a man who has unconsciously swallowed several pieces of glass to make a note of the shape, size, color and character of the pieces after they have been removed from his stomach, in order to describe them in bringing suit to recover from the one who is responsible for his having swallowed them.

On the question of whether or not the plaintiff in this case could recover for mental suffering growing out of his injury, and, if so, to what extent, the court says that it is a familiar principle that, where a physical injury has been sustained, the injured may recover for mental suffering caused by or growing out of his bodily hurt. One may not recover, however, for mental suffering which is not reasonable or which is merely fanciful. It can hardly be disputed that a reasonable fear of death constitutes mental suffering of a very keen sort. It is not unreasonable, this court thinks, for one who has swallowed several pieces of glass to entertain a very vivid and poignant apprehension of an untimely end, and the mental anguish caused by this dread may constitute an element of damage in a suit for damages on account of the physical injury. But after the glass has been removed from his stomach and he is apparently restored to his former condition of health and vigor, his fears, so far as a damage suit is concerned, should cease. He may not continue for an indefinite period to vex his soul with dread on account of having been "cut on the inside" and hold the defendant liable for his apprehensions.

Admissibility of Evidence of Experiments by Experts.

The Supreme Judicial Court of Massachusetts says that one of the questions claimed at the trial of the defendant in the homicide case of Commonwealth vs. Tucker to be material was whether the azygous vein of the victim was severed by the stab in the back, the commonwealth contending that it was and the defendant contending to the contrary. One witness, a medical expert, called by the defendant, on direct examination testified at first, in substance, that while it was barely possible that the vein was thus severed, yet it was highly improbable, and finally said that to him it seemed impossible. He was then asked whether he had made any experiments for the purpose of "ascertaining that opinion," and in reply he said that he had. He was further asked whether or not he had made experiments on a body approximating the size of the body of victim in this case described by him, and he said that he had. But, objection being made, he was not allowed to show the nature of the experiment. This, the court holds, was correct.

Whether the details of an experiment not otherwise material may be shown as having some bearing as substantiative evidence on a question on trial, the court says, depends on the nature of the question and that of the experiment. If, for instance, the question be with reference to the operation, chemical or otherwise, of some natural force which acts uniformly under any given conditions, and the conditions under which the experiment is made are shown to be so similar to those which existed in the case on trial that the court can see that the experiment may be really of assistance to the jury, the details of the experiment may be put in as independent evidence. The true ground of admitting the details and result of such an experiment is that it may be of assistance, but the question whether it may be or whether it may or may not lead to too many collateral questions, is largely within the discretion of the court. It is manifest that in view of the nature of the question in dispute here, namely, whether the azygous vein was cut by the stab in the back, taken in connection with the difference necessarily existing between the conditions in the case on trial and those under which the experiment was performed and the obvious difficulty, if not impossibility, of ascertaining whether such difference had any material effect on the result, the court was fully justified in excluding the experiment or any inquiry into its nature.

It was argued, however, that inasmuch as an expert has the right to explain the reasons for his opinion, it was competent for the witness to state this experiment in detail, to fortify his opinion. But, the court says, it is settled in Massachusetts that the rule allowing an expert to give the reasons for his opinion has its limitations, and one of them is thus stated: "A party can not put in evidence incompetent facts under the guise of fortifying the opinion of his witness, even if the evidence might have been properly admitted on the cross-examination of the expert." The experiment in question being incompetent as substantiative evidence, the court properly excluded all evidence as to its nature, even whether made on a dead or a living body, although offered under the guise of a reason for the opinion of the witness.

1. **Arteriosclerosis as a General Disease.**—Stengel says that three stages of the disease may be recognized: 1. A preliminary one difficult of recognition in its beginnings and confusing to the clinician in his first efforts to distinguish what part the etiologic factors have contributed to the symptom-complex and what part has resulted from the arterial disease itself. 2. A middle period, during which the arterial disease is easy to recognize, but in which secondary organic changes have a rôle of variable importance. 3. A final stage of failure of circulation, organic failure and terminal infection. In the more advanced stages of arteriosclerosis the disease may be classified under the following headings: 1. The thoracic (a) cardiac or disturbances incident on special involvement of the coronary arteries; (b) aortic, referring not merely to aneurism, but also to a sclerotic and calcareous roughening without dilatation but causing embarrassment of cardiac action. 2. Abdominal (a) renal, manifesting itself in the symptoms of chronic interstitial nephritis; (b) intestinal as evidenced by atrophy of the mucous membrane, tendency to chronic colitis, etc.; (c) pancreatic, difficult of recognition, often, however, active in diabetes; (d) hepatic, occurring as cirrhosis; (e) cerebrospinal—most numerous and varied; and (f) arterio-capillary, manifested in moderate circulatory disturbances.

2. **Asthma.**—Arnell reports six cases, illustrating a variety of causes and treatment. The pathology is summed up as follows: 1. A vulnerable mucous membrane. 2. Abnormally sensitive nerve centers. 3. An external irritant or exciting cause. 4. The presence in the body of known and unknown substances which are toxic to patients susceptible to asthma.

4. **Roentgen Ray in Mediastinal Carcinoma.**—Pfahler reports six cases in which carcinoma of the mediastinum developed secondary to carcinoma of the breast. All the patients had been operated on previously. Three of the six patients have apparently recovered, though they are still under observation. In none was any bad result noted.

5. **Cerebrospinal Meningitis.**—Merriman believes that the enormous percentage of mortality in pneumonia among children has been due, in many instances, to unrecognized meningitis. He says that in every case of acute lung involvement in children a careful examination should be made of the spine and neck and eyes. Pressure over the spine and at the base of the skull will bring out the tenderness in the cervical and dorsal regions. Examination of the eyes will sometimes, not always, show some inequality in the pupils, and the presence of photophobia.

7. **New Method of Testing Functions of Digestive Apparatus.**—Einhorn attaches solid food-stuffs to glass or porcelain beads, by drawing them through the opening in the bead and tying them on with silk thread. Examination of the beads found in the feces will reveal the indigestible substances, while those which are digestible will have disappeared during their course

through the gastrointestinal tract. In order to test the work of the stomach alone, a thread is attached to the beads, which are placed in a gelatin capsule. At the end of from four to six hours the beads are withdrawn. By these two methods both the digestion in the stomach and in the bowel may be judged. Einhorn sums up the results of his experiments as follows: In healthy individuals catgut and fishbones are digested in the stomach, whereas boiled or raw meat (beef), raw chicken skin, and raw as well as boiled potatoes, do not disappear altogether in this organ. The muscles show a swelling and loosening of the fibers. Raw muscle fiber and chicken skin disappear in the intestines; tendons remain undigested. Raw potatoes show a varying condition, sometimes disappearing entirely, sometimes going through unchanged. Boiled potato usually seems to be digested in the bowel, but the skin of the potato, raw or boiled, remains unchanged. Fats with a very high melting point, such as lard, are not absorbed in the intestine; suet and mutton fat are digested in the bowel. Fishbone is not changed in the intestinal tract. If the intestinal functions are normal, albumin (raw meat), and starch (potato), boiled two minutes, and mutton fat will disappear during their passage through the digestive tract. Disturbances of these functions may be recognized by the reappearance of food substances attached to the beads. Raw thymus has been used to test the pancreatic function. When the intestinal and pancreatic functions are intact, the thymus will disappear.

8. **What Is the Climacterium?**—Bandler states that although the menopause is generally considered an essential evidence of the climacterium, this is not true. Another erroneous but common view is that after hysterectomy the annoying symptoms of the climacterium are absent if the ovaries be left behind. In point of fact, annoyances of the same nature, often combined with scanty menstruation and with the other evidences of ovarian insufficiency, are often seen in women who have not been operated on, in women at the menopause, or during the climacterium, and even in women who are not near the menopause age. Bandler thinks that we are justified in considering the relative oversecretion of the thyroid in these patients as the pathologic basis, and the probabilities are that ovarian insufficiency means relative hyperthyroidism. The symptoms of diminished ovarian secretion and those of hyperthyroidism are enough alike to warrant the opinion that they are one and the same.

12. **Notes on Cerebrospinal Fluid.**—Pashayan has made a cytologic examination of the spinal fluid in a number of patients, with the object of determining the constancy lymphocytosis in the cerebrospinal fluid in paresis as well as in other mental affections. Among 37 cases of general paresis a marked increase of lymphocytes was seen in 16, a moderate increase in 5; the results were doubtful in 3, and negative in 3. Lymphocytosis was absent in 7 chronic alcoholics, in 6 old syphilitics, in 25 epileptics, in 13 hebephrenics, in 8 katatonics, in 7 manic-depressive cases, and in 7 paranoiac states.

13. **Surgical Rings.**—The object of Shaw's device is to enable the operator to use his fingers instead of forceps, needleholders, etc. The device consists of a pair of steel rings with a small segment cut out on the inner (middle finger) side, and a dentifoliated plate on the outer side (thumb side). These rings fit on the second phalanx of the index finger of each hand. The first and most important use of the ring is in tying sutures and ligatures. In this case the main advantages are that it is ready for instant use and does not weaken the suture or ligature material, as forceps do, and also avoids cutting of the fingers and consequent infection. It enables the operator to separate adhesions with the fingers, without the aid of forceps, gauze, etc., with the least amount of injury to the tissues, and is especially valuable in separating the hernial sac from the cord, and in varicocele. In grasping and retaining tissues, it is much handier and produces less injury than tissue forceps. In the manipulation of the needle it is valuable both as a holder and as a guide in directing the point of the needle among important structures. Lastly, it enables the operator to handle, with ease, slippery viscera, as the intestines.

14. **Contagiousness of Cerebrospinal Meningitis.**—Hare cites a case of cerebrospinal meningitis of unusual severity. In less than thirty-six hours the patient received over 25,000 units of diphtheria antitoxin. The patient died of circulatory and respiratory failure about forty-four hours after the beginning of his illness. Two days afterward Hare was called to see the physician who had had charge of this patient. He found him with slightly injected conjunctivæ and suffering from a condition of discomfort in the back and legs, which did not, however, amount to pain. No rigidity was present in any part of the body. On the evening of the same day this second patient was unconscious and in violent convulsions, accompanied by attempts to vomit which were prevented by the tightly clenched jaws. The Kernig sign was present, the hands were clenched with the thumbs in at the palms, the head was rotated sharply to the right, and there was also a conjugate deviation of the eyes, to the right, with fixation of the eyeballs. The physician died about eight hours after the development of distinct meningeal symptoms and nineteen hours after his first symptoms developed. Hare considers these two cases of interest not only because of their violence, but also because it seemed that the infection was transferred directly from the first case to the second. Another point of interest is that the first patient had visited four days previous to his illness in two cities which at that time were the seat of an epidemic of cerebrospinal meningitis. Still another point of interest is that a medical student who helped take care of the patient developed a violent tonsillitis, with fever and pain throughout the body. Hare himself suffered from a chill, fever of 102, and severe aching in the neck, back and limbs four days after seeing the first patient and within twelve hours of seeing the second one.

16. **Education in Sexual Subjects.**—Valentine summarizes his paper as follows:

1. Sexual physiology and hygiene need not be formally taught girls, save in the exceptional instances in which the genetic impulse is prematurely developed.
2. Sexual physiology and hygiene should be taught every boy, when mental and sexual puberty make him capable of beneficially utilizing the knowledge.
3. The nature and scope of instruction on sexual subjects should be regulated according to each pupil's ability properly to appreciate the warnings inseparable therefrom.
4. The age at which a person may safely be instructed in sexual subjects is that age at which, in each individual case, such instruction becomes necessary for the purposes of moral and physical prophylaxis.
5. The individuality of the parent, physician or teacher should be the guide to the choice of one or the other as the exponent of the facts.
6. Educational institutions may be utilized for instruction in sexual subjects, but such instruction must be given to small groups of pupils selected because of their mental parity as nearly as may be.
7. Text-books on elementary hygiene should not contain chapters on sexual physiology. Those charged with imparting instruction on sexual subjects should be provided with separately printed chapters on the physiology and hygiene of these matters. These separately printed chapters could then be given with the greatest discretion to such pupils only whose mental development would preclude their misusing the information derived therefrom.
18. **Surgery of the Thyroid.**—Ballin's experience is limited to 6 cases. He considers that 3 patients are cured, 2 very much improved, and one slightly improved. All these cases were very bad ones, with pulse over 140, severe nervous symptoms and intestinal disturbances. In each of these 6 cases he did a thyroidectomy, removing half or more of the diseased gland. He believes that this should be the operation of choice, if internal treatment fails.

23.—This article appeared elsewhere.

24. **Vaginapexy.**—This operation, which is used in cases of extreme vaginal relaxation, such as prolapse, incomplete and complete procidentia and advanced cystocele, is described by Graves (the operation was devised by W. H. Baker) as follows: The patient is placed in the Trendelenburg position and a small median abdominal incision is made. The intestines are packed away with gauze in order thoroughly to expose the posterior cul-de-sac. Beginning first on the right side, a point is selected a little posterior and external to the peritoneal reflexion of the posterior cul-de-sac from the wall of the uterus. This point is then seized with the bullet forceps, the forceps being carried deep enough in order actually to seize the wall of the vault of the vagina. In order to ascertain whether or not the wall of the vagina is included within the teeth of the bullet forceps it is a safe plan to have an assistant insert his finger in the vagina so that he can give information as to whether the vagina is really being drawn up by the traction of the bullet forceps. When it is found that the vagina is firmly grasped, a silk suture, preferably No. 10 braided silk, is passed through the tissue to take the place of the bullet forceps. The suture is then passed up through the peritoneum, rectus muscle and fascia of the abdominal wall about one-half to three-quarters of an inch from the incision. It is then passed back again into the abdominal cavity and included with the other end of the suture in a pair of snaps. The same procedure is then carried out on the left side and the two sutures tied, drawing the vagina firmly up to the anterior abdominal wall and completely anteverting the uterus, the knots being thus left within the abdominal cavity. The abdominal incision is then closed with great care, in layers. In passing the suture through the floor of Douglas' pouch Graves has found it advantageous to employ the stitch devised by Max Broedel for the suspension of prolapsed kidneys, as it gives far greater tensile strength. It is necessary, however, to avoid carrying the suture through into the vaginal cavity.

31. "Two Unusual Complications of Labor. F. S. Clark, Cleveland.

31. **Unusual Complications of Labor.**—In the first patient mentioned by Clark, the lower portion of the vagina was entirely separated from the upper by a transverse membrane. The anterior attachment of the membrane was about one and a half inches and the posterior about two and a half inches from the vulva. Pressure against the membrane showed it to be firm, except at one point toward the left side, which yielded slightly. The color of the membrane was the same as that of the vaginal mucosa. Its thickness was about that of ordinary blotting paper. The second case was one of congenital displacement of the urinary bladder. The cavity of the pelvis was well filled with what appeared to be a cystic tumor attached to the left pelvic wall. The tumor disappeared on catheterizing. The catheter had to be passed upward, inward, to the left and then downward before the urine would escape.

33.—See abstract in THE JOURNAL, Dec. 16, 1905, page 1899.

34. **Fracture of Femur.**—Dubs reports a case of oblique fracture of the middle third of the femur in which there was a marked tendency to shortening. The ambulatory method of treatment was chosen. At the end of two weeks and five days the patient was allowed to get up and walk about with crutches, elastic traction being still applied. At the end of four weeks and five days traction was dispensed with. Five weeks and two days after the accident the patient was allowed to discard the crutches most of the time. Eight weeks after the accident the splint was removed altogether. Skiagrams taken one year after the date of the fracture show a perfect union and no deformity of bone.

36.—See abstract in THE JOURNAL, Dec. 16, 1905, page 1901.

37. **Early Arrest in Infection.**—Laplace states that the problem to be solved is the removal, so far as possible, of all the organisms which have entered the lymph vessels and are already beyond the reach of an antiseptic. Laplace accomplishes this by a squeezing or milking process of the wound. The parts around the wound are pressed on and a certain amount of serum exudes. This serum contains the staphylococcus and streptococcus, even after the wound has been squeezed four or five times, showing that the organisms invaded the lymphatics. When the hemorrhage stops, Laplace cauterizes the wound with pure carbolic acid. This causes a fresh hemorrhage. Further squeezing facilitates the flow of blood, and also increases the subsequent flow of serum or lymph. A dry dressing completes the treatment. If the case presents evidence of a marked and spreading infection, Laplace also scarifies the redlined area in addition to the procedures just mentioned. When the lymph channels are thoroughly emptied an ice-cold antiseptic solution is applied to the parts for the purpose of giving direct entrance of the antiseptic into the affected lymph channels laid open by the scarification, in this way destroying the germs which may linger within the lymphatics. The solution used consists of one part of bi-chlorid of mercury to five parts of hydrochloric acid and 1,000 parts of water. Should pain result from this application the solution is made weaker. Internally, Laplace administers from 10 to 20 drops of tincture of chlorid of iron. He has followed this method of treatment in the case of minor wounds, and as infective cuts, scratches, excoriations, infected pimples, and erythema from starting erysipelas, for a number of years, and has always succeeded in checking the infection.

44. "Case of Malformation of the Duodenum. C. J. Habbegger, Watertown, Wis.

41.—See abstract in THE JOURNAL, July 1, 1905, page 67.

42. *Id.*

44. **Malformation of Duodenum.**—The malformation reported by Habbegger occurred in a newborn infant that lived about five days. On the lesser curvature of the stomach there was a deep furrow which divided the organ into two parts, and which, if a little more marked, would have produced the anomaly known as the hour-glass stomach. Just below the pylorus, which was normal, the stomach emptied into a cul-de-sac about the size of an orange which had no communication with the rest of the intestinal tract. This cul-de-sac was lined by a mucosa which differed from that of the stomach and corresponded with that of the duodenum. That part of the intestinal tract corresponding to the descending portion of the duodenum commenced in a narrow part as a continuation of the common duct. Clinically the condition present was identical with pyloric stenosis.

45. **Value of Ergot in Obstetrics.**—Davis states that he is accustomed to use ergot in some form in the great majority of cases of labor. The only contraindication to its employment is excessive hemorrhage with a depleted condition of the vessels and a feeble heart. Strychnia is given with the ergot, because it rouses the ganglia of the uterus and stimulates the patient's nervous system. Davis never gives more than two drams of ergot by mouth at one time. He has never witnessed any untoward results from the use of ergot. Hirst uses ergot as a routine practice in all cases of labor as soon as the child is born. A very irritable stomach and persistent vomiting are contraindications to its use, but even in these cases, after the labor is over, Hirst has succeeded in having the ergot retained. If it has been necessary to anesthetize the patient he gives a deep hypodermic injection of ergot into the thigh as soon as the uterus is evacuated. In the case of twins, he has been in the habit of giving a dram of ergot by mouth after the birth of the first child, if there is nothing about the condition of the second child to obstruct labor. Cameron uses ergot in all cases of labor, unless specially contraindicated, after the uterus is emptied. He has never seen any untoward effects or accidents attributable to the use of ergot.

53. **Commercial Therapeutics.**—Luy says that when physicians prescribe a preparation which is said to contain certain drugs, without knowing the exact amount of each constituent to the dose or their physiologic action, they are pursuing a course which disregards every teaching prescribed by a reputable medical school. They can not know whether new symptoms, if they should arise, are due to the medicine or to the original condition of the patient. They are in absolute darkness so far as the interest of the patient is concerned. If dangerous symptoms follow such treatment they may be misled in their efforts to control them. The great mass of testimonials which laud many preparations so highly are born of ignorance and the evident desire of the author to see his name in print. Mushroom drug manufacturers, without a grain of medical knowledge, are springing up on every side with wonderful cures for diseases which heretofore have been hopeless cases. Luy says that a most unfortunate feature of this situation is that some reputable medical journals are advertising this rot to the medical profession. If the profession did not support the manufacturers of this material the manufacturers would not continue in business. Luy asserts that the tendency of the present, so far as medical therapeutics is concerned, is decidedly non-progressive. If physicians wish to remain true to the interests of their patients, to the profession and to themselves, they will refuse absolutely to prescribe any preparation which is not accompanied by a complete formula of its contents, as well as the amount of each constituent in a given quantity.

55. **Scopolamin-Morphin Ethyl-Ether Anesthesia.**—By carefully investigating the effects of scopolamin-morphin ethyl-ether anesthesia on 150 patients, before and after operation,

from the head nurse in charge, from the patients themselves, and by personal observation, Rice found it a very valuable addition to his method of anesthesia, which is as follows: About half an hour before the operation the patient is given 1/100 gr. scopolamin and 1/6 gr. morphin hypodermically. The general anesthesia is begun with bromid of ethyl, which he has used in from 2,000 to 3,000 cases. He always uses the drop method on the Eschmarch mask until the air passages become accustomed to the slight irritation; then, when the patient has become unconscious, he pours on the mask about half dram of the bromid of ethyl and at once covers the mask with gauze or a folded towel. The patient, after a deep inspiration or two, begins to relax, and after two or three more, Rice changes the mask for the ether cone, and in nearly every case, unless an unusually robust man, the patient passes from the ethyl anesthesia to that of the ether without a struggle. In 150 consecutive cases in which he used the scopolamin and morphin, fully 75 per cent. of the patients were scarcely nauseated; about 20 per cent. vomited a dram or two of mucus, and about 5 per cent. vomited freely, this in many instances being doubtless due to an irritable condition of the stomach before the anesthesia.

62. **Treatment of Trachoma.**—The treatment employed by Pratt consists in thoroughly massaging the everted lids with borie acid powder. The massage pressure is made by a cotton-wound probe. The partially dissolved powder is allowed to remain under the lids. The eye is bandaged and cold applications are applied. This treatment is repeated after three days and is continued until there is no further evidence of the disease. No scars result and the treatment has been entirely satisfactory to Pratt in about twenty cases in which it was employed.

- 67 Typhoid Fever in Children. L. C. Ager, New York.
- 68 Case of Tumor of Cerebellum with Necropsy. C. F. Judson, and C. D. Camp, Philadelphia.

65. **Unusual Case of Tuberculosis.**—The patient, whose case is reported by Townsend, was the second child of exceptionally healthy parents. The family history was good. The only cases of consumption in the family were remote and occurred in collaterals. The food of the child was breast milk for the first seven months, at the end of which cow's milk, modified with cereal water, was given. This milk was of the best, coming from cows that were frequently tested for tuberculosis and whose milk was used especially for infants. The infant received no other food. At the age of nine months the child was suddenly taken sick with fever and vomiting. The fever continued for over two months and ended in death. During all this time nothing was found on physical examination, except a slight otitis media of one ear. The drum was punctured and a thin serous fluid escaped. Several times in the course of the disease the ears were examined, but nothing abnormal was found, so that otitis as a cause of the fever was ruled out. In this way several other causes of fever were eliminated. The fever varied irregularly from 100 to 104 F. and was often higher in the morning than at night. On several occasions it became normal and once or twice it was subnormal. The general course of the fever was lower during the last two weeks of the disease. At the end, however, it mounted rapidly above 106 F. The infant's digestion was good during nearly the whole course of the disease. During the last month, however, vomiting and disinclination to take food became prominent features. Bile was often vomited. There appeared to be no

evidence of intestinal or of gastric indigestion, or of accumulation from pyloric stricture, and it was believed that the vomiting was reflex from the fever. Thorough evacuations with calomel had no effect on the fever. The autopsy showed extensive tuberculosis throughout the peritoneal cavity.

Indiana Medical Journal, Indianapolis.

January.

69. *Observations of Tuberculosis Sanatoria in the West. T. Potter, Indianapolis.

70. *The Cigarette; Its Relation to Mental and Nervous Diseases. W. B. Fletcher, Indianapolis.

69. **The Tuberculosis Sanatorium.**—Potter, secretary of the Indiana state tuberculosis commission, presents the following conclusions arrived at by the committee as to the institutional treatment of tuberculosis: First, the sanatorium plan has decided advantages over any other for most cases. Second, this plan of treatment does not require very expensive buildings nor an elaborate plant, provided the chief purposes of the plan are kept in view. Third, the method and skill of the management are of more importance than the material equipment. It is the men behind the guns who contribute most to success. Fourth, the great majority of the patients easily, cheerfully and quickly fall into line with the regulations and life of a well-managed sanatorium, just as do the great majority of students in an educational institution. Fifth, a notable spirit of cheerfulness and hopefulness prevails in a well-managed sanatorium. Sixth, in a large proportion, about 70 per cent., of cases of early pulmonary tuberculosis, the disease may be arrested and the patients returned to useful activity by this plan of treatment, intelligently and faithfully carried out. Seventh, it was the universally expressed belief by the medical officers of western sanatoriums visited by the commission that, at least approximately, good results could be obtained by a similar plan of treatment in any climate. Eighth, the committee was everywhere impressed by the emphasis put on the educational value of these sanatoriums in the crusade against tuberculosis. Ninth, everywhere and always in these institutions tuberculosis is emphasized as being an infectious disease. The most stringent precautions, therefore, are taken against the spread of this infection. These measures, very simple and easily practicable when understood, practically insure against danger. It has come about, therefore, that one of the places of greatest safety against tuberculous infection, among the habitations of men, is the sanatorium for the treatment of this dread disease. All the inmates evidently feel so, because they make it so.

73. *The Association of Epilepsy with Muscular Conditions Fitting Best into the Cadre of the Myopathies. A. Onuf, Sonyea, N. Y.

74. Multiform Tie Including Automatic Speech and Purposive Movements. M. Prince, Boston.

72. **Two Unusual Brain Tumors.**—The first case reported by Gordinier and Carey was a multiple cylindroma of the base of the brain, involving the second, third, fourth and eighth cranial nerves, and producing symptoms closely simulating a tumor of the quadrigeminal bodies. Death resulted from exhaustion. The second case was a neuroepithelioma of the choroid plexus of the fourth ventricle, growing dorsally and producing symptoms characteristic of a tumor of the medium lobe of the cerebellum. There was no history of having received an injury to the head.

73. **Epilepsy and Myopathies.**—Onuf reports 6 cases of epilepsy in which the patients presented partly muscular atrophies, partly defective muscular action without clearly demonstrable atrophy, but with definite distribution of these disturbances, manifested, on the whole, as follows: Wing-like standing off of the scapulae, due, apparently, chiefly to weakness of the trapezius, possibly also of the serratus magnus, rhomboides, and levator anguli scapulae muscles; atrophies of

the scapular muscles in a strict sense, namely, the infraspinatus and the supraspinatus; also occasionally of the deltoids and other muscles of the shoulder joints; lordosis of lumbar spine in erect position, disappearing in sitting position, a phenomenon clearly explained by Gowers in "pseudo-muscular hypertrophy" as due to weakness of the extensors of the hip, causing an inclination of the pelvis forward and compensatory bending backward to the body; pes valgus; involvement of the facial muscles (2 cases only); electrical changes manifested most frequently by a reversal of the galvanic formula, particularly in the deltoid muscles; fibrillary twitchings (2 cases). This muscular symptom-complex was not present in all cases alike nor in the same degree. In some cases the lordosis was chiefly developed, in others the wing scapulae; and the flatfoot was present in all cases but one; the facial involvement was found in only 2. Qualitative galvanic changes were found in at least 4 cases; fibrillary twitchings in 2. Onuf states that the distribution of the muscular disturbances conforms best with that of the myopathies, but the presence of qualitative electrical changes (reversal of the galvanic formula) found in at least 4 cases, and the presence in 2 cases of fibrillary twitchings, speak rather against it. Of interest is the association of the malady with epilepsy—an association which Onuf has not found mentioned in any of the familiar text-books on nervous diseases. The interesting question arises whether or not a case of epilepsy thus complicated can be called idiopathic.

80. Tuberculin as a Diagnostic Agent. W. R. M. Kellogg, Seattle, Wash.

78. **Tuberculosis of Urinary Tract and Male Genital Organs.**

—Hawley suggests the following rules: 1. In all cases of hematuria (especially transient hematurias of doubtful cause), always bear in mind the possibility of tuberculosis. 2. Every cystitis, not due to the gonococcus or infection from without, should be considered suspicious of tuberculosis and be subject to careful observation. 3. In all suspected cases the patients should be subjected to thorough and repeated examinations. 4. Until a positive, simple method is at hand for identifying the tubercle bacilli in the urine we are not warranted in claiming their presence, except when found in large numbers, unless we have taken steps to procure a urine free from smegma bacilli. 5. In all suspicious cases evidence of tuberculous lesions in other parts of the body should be sought. 6. When the slightest doubt remains concerning any case the tuberculin test should be used. 7. A diagnosis is never complete until the source of infection has been traced.

79. **Acute Typical Pulmonary Tuberculosis.**—The previous history of Johnson's patient shows that she had suffered from the ordinary diseases incident to childhood. While returning home from a party she became wet and contracted what she thought was a severe cold. For two weeks following she suffered from shortness of breath on much exertion, loss of appetite, general depression, and pain over her left side, not localized. Her temperature was 98.5°; pulse 110 and feeble; respiration was rather hurried; there was no cough and no expectoration; moderate dyspnea; slight cyanosis. On auscultation no râles were detected, and percussion revealed no areas of dullness. The tongue was slightly coated, bowels regular, urine normal. The pain complained of over the left side of the chest, and which at times extended down the anterior part of the left thigh, was diagnosed as neuralgia of the intercostal and anterior crural nerves. The patient was put on a tonic treatment and advised to take a vacation of a month, which she did. During this time her physical condition was carefully studied, inasmuch as no positive diagnosis had yet been made. At the end of a month she was sent to the hospital.

By this time the symptoms were nearly all aggravated. A thorough physical examination revealed nothing more abnormal and the case remained undiagnosed. After diligent search for the tubercle bacilli the results were negative. Seven weeks after her admission to the hospital a third microscopic examination of the sputum revealed an enormous number of tubercle bacilli and a diagnosis was made of acute pulmonary tuberculosis.

81. **Trypanosomes and Disease.**—Ward reviews what is known as trypanosomes, and points out their relationship to disease in the human species. Speaking of the *Spirochæta pallida*, he says that it would be natural to expect that this group of flagellates, which contains so many disease-producing organisms that attack lower animals, should yet furnish the explanation of the etiology of human diseases hitherto unexplained. In maladies which are evidently of germ production, it is more likely that the cause is to be found among the unstudied protozoa rather than that the refined technic of the modern bacteriologist has been unsuccessful in detecting the plant germ which produces it.

82. **Variations in Hernia Operations.**—Lord considers that the Bassini operation for inguinal hernia occupies first place, because it has stood the test of time. In exceptional cases, however, he thinks that the newer methods are to be preferred because departure from routine methods is necessary in some cases of inguinal hernia.

84. **Scopolamin-Morphin Anesthesia.**—For four years Getzlaff has employed this method of producing anesthesia, following the suggestions of Korff. He says he has yet to see the first case of headache, vomiting, disturbed digestion, retention of urine, and especially intestinal paresis, after abdominal operations, although occasionally, in very choleric patients and after insufficient preoperative preparations, a peculiar muddy discoloration of the skin and a not very agreeable so-called bilious smell emanating from the patient but soon passing off, has been observed by him. The ages of his patients ranged from 10 to 80 years, and the number operated on is over 90, with only one death, which occurred twelve weeks after the operation from other causes. His series includes about 40 abdominal sections.

1. **Spread of Carcinoma.**—Lockwood claims that the rapidity with which cancer spreads into the lymphatics depends to a large extent on the position of the primary growth. When that is situated within a hollow muscular organ, such as the urinary bladder or gall bladder, the pause may be a long one; but when the growth is in the mammary gland, in the tongue, or in the pharynx, he believes that there is hardly any interval between the onset of the growth and its spread into the neighboring lymphatics. In cancer of the breast he has found that the tumors in the lymph glands soon grow larger than the tumor from which they sprung, even though the presence of the growths in the lymph vessels can not be seen during the operation, except, occasionally, in very advanced cases. Lockwood advises the use of the microscope in all cases. He considers the duct carcinoma to be as malignant as any other variety. He also thinks it probable that cancer may cross in the lymph channels from one breast to the other, and cites one instance of carcinoma spreading against the lymph stream.

2. **Swellings of the Breast.**—Clark discusses the differential diagnosis of neuralgia of the breast, mastitis, abscess, cysts,

and benign and malignant tumors. He considers the following the ideal way of examining a breast that is the seat of a swelling:

The patient should preferably be seated in an ordinary chair, with her arms hanging down and the doctor seated opposite. If for any reason she has to be in bed, she should be placed flat on her back, with her head and shoulders slightly raised, and her arms lying beside her, the doctor standing at the left side of the bed; a shawl may be thrown loosely over the shoulders, otherwise the upper part of the body should be completely uncovered. Inspection is the first thing. The surgeon looks at the two breasts, noticing particularly any enlargement of either, or any puckering of the skin, also any alteration in the normal appearance of the nipple, and whether the two nipples are exactly opposite one another. If they place his hand at the upper breast, he can feel it all over. If he detects no tumor by manipulating in this way, he may be satisfied that there is not one. Should he feel a tumor, he will first notice whether it is tender or not, then satisfy himself whether it is circumscribed or diffuse; then, by lightly moving his hand laterally to and fro, whether the skin is adherent to it; then whether it is adherent to the pectoral muscle; and to ascertain this it is well for an assistant to support the arm and alternately to relax and to tighten the pectoral. The next thing is to examine the tumor with the two fingers, ascertain its relative hardness and to decide whether there is fluctuation or not, and, lastly, the axilla and supraclavicular region should be examined for enlarged glands. In doing this the arm should be supported, and the muscles forming the axilla relaxed, and two fingers of the right hand employed. The whole axilla should be felt, more particularly the outer part, as there are usually glands found enlarged along the line of the axillary vein, if there are any. The forefinger should carefully feel the head of the above-mentioned muscle and the back edge of the sternomastoid muscle. It is desirable also to examine the axilla of the unaffected side, as some people have enlarged glands from another cause, and the enlargement on the affected side may not be due to the condition of the breast.

3. **Enucleation of Prostate for Hemorrhage.**—Thomson advocates the removal of the prostate for hemorrhage that can not be controlled otherwise. He cites one case in support of his contention.

4. **Ventral Fixation.**—Sinclair states that the operation of ventral fixation of the uterus, when properly carried out, is a most valuable one in the treatment of displacements of the uterus.

5. **High Operation for Varicocele.**—Corner and Nitch detail the results in 100 cases in which the high operation for varicocele was performed. After exposing the cord by a short incision, the pampiniform plexus was isolated, ligated in two places, about two inches apart, and the intervening portion excised. In some cases the two ends were approximated by a suture which transfixed the stumps. In 2 per cent. of the cases some recurrence of the varicocele was noted, but in neither instance was there any pain or discomfort. An inguinal hernia was present in 2 per cent. Two patients had a spermatocele. In 8 per cent. there was a tense hydrocele, and in 15 per cent. there was present a flaccid hydrocele which did not cause any symptoms. In 84 per cent. the sensibility of the testes was unaltered; it was increased in 9 per cent., decreased in 5 per cent., and lost in 2 per cent. Four patients stated that they were worse after the operation. Twenty-six reported themselves as being neither better nor worse; 70 patients were definitely improved and well satisfied.

7. **Extensive Operation for Carcinoma.**—In the case reported by Childe the greater portion of the transverse colon was excised, not because it was involved in the disease, but on account of the necessity of sacrificing its blood supply in order to get wide of the growth. About one-third of the stomach, at the cardiac end, was not removed so as to permit of a gastrojejunostomy. The growth infiltrated the anterior and posterior walls of the stomach for about half their extent. The pancreas was firmly attached to the stomach. The four openings made in the gastrointestinal tract were all closed with a double row of continuous silk suture. No button or bobbin of any kind was used. Five weeks after the operation the patient was up and about, taking ordinary solid food of digestible quality, and not in too large quantity, and was rapidly gaining in weight and strength.

12. **Budde Process for Preserving Milk.**—With a view to testing the efficiency of the Budde process for the preservation of milk, Hewlett conducted a series of experiments, from the results of which he draws the following conclusions:

1. All the non-sporing organisms, pathogenic and non-pathogenic, dealt with—viz., the *Bacillus tuberculosis*, the *Bacillus diphtherie*, the *Bacillus acid lactici*, the *Bacillus typhus*, the *Bacillus coli communis*, the *Bacillus dysenteriae*, a paratyphoid bacillus, the *Micrococcus pyogenes aureus* and the cholera spillum—are destroyed by the process.

2. Sporing forms—viz., the *Bacillus anthracis*, the *Penicillium glaucum*, the *Bacillus subtilis*, and the *Bacillus mycoides*—are not destroyed by the process although reduced in numbers, the inference being that the vegetative forms are destroyed but the spores are not destroyed.

3. Although the heating *per se* may be efficient in destroying certain non-sporing organisms—e. g., the *Bacillus diphtherie*, the *Bacillus typhus*, and the cholera spillum—it is not so in all cases. Thus in one experiment the *Bacillus typhus* and the *Micrococcus pyogenes aureus* survived the heating when no peroxid was added, and under similar conditions the *Bacillus acid lactici* survived in two experiments in which this was tested.

4. The same fact is strikingly shown by the effect of "Buddelising" on the natural milk—i. e., the milk without added micro-organisms. The reduction in numbers effected by heating alone is far less than with "Buddelising."

5. "Buddelised" milk is practically indistinguishable from untreated milk in taste, odor, appearance, and in the rising of the cream. No increase in acidity is caused by the treatment.

6. "Buddelised" milk will keep perfectly sweet and apparently unaltered in odor, taste, and appearance for at least from eight to ten days in hot weather and for a still longer period in cold weather.

7. In milk obtained in the ordinary way without special precautions the micro-organisms are reduced by the Budde process over 99.9 per cent. In the milk kept at room temperature the amount of residue of living micro-organisms multiplies daily and ultimately (after from 12 to 14 days) may cause the milk to go bad.

8. The distribution of the "Buddelised" milk in closed bottles is in itself a great improvement on the routine system of distribution in open vessels.

9. The method excludes all possibility of adulteration of the milk by the vendor before it reaches the consumer.

10. Properly carried out, the whole of the added hydrogen peroxid is decomposed at the end of the process and no trace of it can be detected in the treated milk.

The principle of the Budde process is as follows: The milk is obtained in as cleanly a condition as possible, and if it has to be kept for any time before treatment it is efficiently chilled, but usually it is treated soon after milking. A proper proportion of peroxid of hydrogen is added to the milk and the mixture is heated to from 51 to 52 C. for at least three hours. A temperature below 48 C. is not efficient and one above 55 C. should be avoided as this tends to induce changes in the milk. With the aid of the heating the hydrogen peroxid is completely decomposed into water and oxygen by an enzyme (catalase) present in the milk, and the oxygen at the moment of liberation being in a nascent condition acts as an efficient germicide. At the end of the process the whole of the hydrogen peroxid should have been decomposed, provided the right proportion has been added, so that no antiseptic remains, a small but inappreciable addition of water has been made to the milk, and the majority of the micro-organisms have been destroyed. The amount of hydrogen peroxid required to obtain this result is about 15 c.c. of a 3 per cent. solution per liter of milk, so that the quantity of water added to the milk amounts to about 1.5 per cent., which, on a basis of 3 per cent. of fat, would reduce the percentage of fat to 2.95 in the treated milk, a reduction in the percentage of fat of about 0.05, an amount which may be regarded as negligible. The milk is treated in bulk and immediately bottled with suitable precautions and supplied to the public in the bottles, a fact which alone should commend it. The milk so treated is practically unaltered in appearance and flavor, the cream rises as usual, all ordinary non-sporing pathogenic germs are destroyed, and the milk will keep sweet for at least eight or ten days in hot weather.

14. **Interrupted Circulation in Rheumatoid Arthritis.**—Ewart emphasizes the efficiency of this method in reducing the swelling and the pain associated with the intra-articular effusion of synovial fluid, or the para-articular effusion of lymph. He says that the immediate relief afforded in cases of acute arthritis, whether rheumatic or gonorrheal, and in cases of sprain, is equally striking. In joints chronically thickened or fixed the improvement reported has not resulted in a complete cure.

17. New Triple Staining Process.—Bonney's technic is as follows:

1. Fix small pieces of the tissue in acetic-alcohol. (The fixatives of Hornum and Flemming may be used if preferred. The older and inferior fixatives such as alcohol, are useless as regards the fine details for which this process was devised, whilst formalin renders it impossible of performance.)
2. Embed, cut, and mount in the usual manner.
3. Stain for one hour in a saturated watery solution of safranin.
4. Wash in water.
5. Stain for a quarter of an hour in a saturated watery solution of methyl violet.
6. Wash in water and wipe the slide dry except that occupied by the section.
7. Immerse the slide in a drop bottle the following solution: to 20 cubic centimeters of acetone add drop by drop a saturated watery solution of orange G, until the flocculent precipitate which slowly appears on shaking is just dissolved in excess of the watery solution; then filter. S. Flood the slide with this solution. A cloud of color immediately comes out which obscures the view of the section.
8. Pour this off on to blotting-paper and flood again with the same solution. The color cloud being much fainter the section can be watched.
9. When the section has attained a rather faint brownish-pink color, pour off the orange acetone solution.
10. Wash in acetone for a few seconds.
11. Transfer to low-power microscope and see if the proper result has been attained.
12. Wash in two fresh changes of xylol.
13. Mount in xylol-balsam.

All chromatic elements, nucleoli, and certain nuclei, such as those of polymorphonuclear leucocytes, stain a rich violet, chromosomes standing out with peculiar distinctness. The spindle fibers of nuclear mitosis stain a faint pink. The cytoplasm stains a rose pink. The intercellular tissue stains a pale yellow. These effects are best seen if the slide be examined through a deep blue screen.

20. Chitral Fever.—McCarrison describes this affection as an acute infectious disease epidemic in the Chitral Valley during the summer months and characterized by a single paroxysm of fever of typical course which persists for about three days without marked local affection. The paroxysm is accompanied by severe headache, pains in the back, bones, joints and muscles, and is followed by severe prostration, which continues for ten days or more after the attack. The virus of the disease is unknown. It does not seem to be contagious and requires a high atmospheric temperature for its development. As a rule, one attack confers immunity. Complications, with the exception of a terminal bronchitis, are few. The mortality is nil. The treatment is symptomatic.

29. Operative Treatment of Exophthalmic Goiter.—Friedheim declares that enucleation or resection of part of the struma is the only means known to date by which exophthalmic goiter can be permanently cured. He reports his experience with 20 cases. Fourteen patients were completely cured, the interval since the operation ranging from four to nearly sixteen years. Five were improved to such a degree that they can support themselves, one by sewing, the others as saleswomen. In 3 cases the patients realize that great improvement was effected,

but as some of the symptoms still persist they are being advised to submit to another operation. One of the patients has died; possibly too little of the thyroid gland was left. This assumption was confirmed by the fact that the severe tetany observed subsided under thyroid tablets. In one case the right lobe was enucleated, but the symptoms by the end of the year were nearly as bad as at first. The left lobe was then extirpated and the patient was permanently cured. This was eight years ago. The statistics from four large clinics show 75 permanent cures and 23 much improved out of 109 cases, with 8 deaths. With internal treatment the mortality is estimated at 12 per cent., and permanent cures seem to be out of the question, he says.

30. Operative Treatment of Suppurative Meningitis.—Kümmell reports a case of a severe meningitic process following fracture of the base of the skull. Pus was evacuated by lumbar puncture and the patient—a healthy man of 33—recovered after bilateral and extensive trephining. Kümmell's experience has been that lumbar puncture will afford great relief, even when the process is too far advanced for hope of recovery.

31. Spinal Analgesia.—Donitz reviews his experience with 407 cases in which spinal analgesia was induced for operations. Cocain was used in 296 cases, stovain in 102 and eucain in 7. One of the reasons for the occasional failures observed at first was that the needle had been inserted in the cauda equina, not in the open space. If a tube is full of fluid, holding it slanting does not change the position of the fluid, but if it contains only a little fluid this flows to the lowest point when the tube is slanted. If the cerebrospinal fluid is under high pressure, raising the pelvis does not change its position, but if there is only a small amount in the spinal cavity raising the pelvis allows it to flow toward the head. The by-effects of spinal analgesia are those of an aseptic meningitis. They can be avoided by using the least irritating substance as a vehicle for the anesthetic and the smallest possible amounts. The ideal method, Donitz thinks, would be to inject the anesthetic directly into the segment of the spinal roots which correspond to the region on which the operation is to be performed. The danger of injury to the spinal cord renders this impracticable, but this ideal is approximated by making the injection as high as can safely be done, that is, between the second and third or first and second lumbar vertebrae, and then, by raising the pelvis or by constriction of the neck, forcing the anesthetic indirectly to the desired point. In cases of by-effects, castor oil seems to be useful. He remarks that in operating on the abdomen it is of no benefit to have the legs and pelvis anesthetized also. It is sometimes possible to accomplish the desired result with as little as 1 c.c. of the solution, if the pelvis is raised. When the cerebrospinal fluid is very scanty it is wise to use more of the vehicle. This is done by aspirating a little of the fluid into the syringe instead of merely injecting the anesthetic into it. This dilutes the anesthetic and insures its better diffusion. In case of deficient flow of the cerebrospinal fluid it is wiser to refrain from spinal anesthesia for operations at the umbilicus or above, for fear that it may prove a failure.

32. Magnesium Plates in Suturing the Liver.—Payr describes considerable experimental work which demonstrates the ease and security with which the liver can be sutured after resection, when the stitches are taken through holes in a couple of magnesium plates as stays. He gives a number of illustrations to show the technic and the results.

33. Primary Tuberculosis of the Muscles.—Kaiser reports a case in a woman of 70 and reviews the 17 cases recorded in the literature. The other patients were mostly young and recovered after operative treatment.

35. Malignant Disease in the Kidneys: Hypernephroma.—Albrecht has had occasion to observe, at Hochneegg's clinic, 28 cases of a malignant tumor in the kidneys derived from suprarenal tissue. In 18 cases the tumor was on the left side. Hematuria was noticed in only about a third of the cases. Local pain was a frequent symptom; in some cases it was noted from four to fifteen years before the true nature of the trouble became manifest. In a few instances there were

digestive disturbances. A differential point is that the symptomatic varicocele accompanying the growth does not subside as the patient reclines, like ordinary varicocele. The age of the patients ranged from 28 to 66. A very important feature of these cases is the metastasis. Frequently the metastasis in some bone is the first revelation of the hypernephroma. This occurred in 4 of the total 28 cases. In one the metastatic tumor was in the forehead, in another in the femur, knee or clavicle. The possibility of a primary hypernephroma should be suggested by the discovery of a rapidly growing, solid tumor in the bone in a person between 40 and 66. The urine should be repeatedly examined. The findings were negative in only 1 of these 4 cases; in the others the urinary findings gave the clue to the nature of the trouble. Treatment should be nephrectomy; partial resection, he thinks, is dangerous. Operation was undertaken in 24 cases, and of the 16 patients who survived the operation 9 have since died from local recurrence or metastasis and another from intercurrent pneumonia without a trace of recurrence. A tendency to tardy metastasis is manifest. Of the 16 patients who survived the operation, only 4 remained healthy for more than four years, and 3 of these 4 developed metastases after that interval. Consequently there is only a single patient in good health to-day, after an interval of four years or over, out of the 24 operated on within the last ten years. The article concludes with a study of other features in regard to these growths and their mode of development, both anatomic and clinical.

38 Endemic Cancer Among Brook Trout.—Pick has been investigating the thyroid cancer found in a salmon and has found it to be identical with the "gill disease" endemic among salmon and brook trout in certain parts of the world. Bonnet in 1883 reported the loss of 3,000 lake trout in the fish hatchery at Gardasee from the rapid growth of tumors on the floor of the mouth and gills. A similar endemic was reported from Scotland in 1888 and from New Zealand in 1901. Nothing of the kind has been observed in the hatcheries in Germany. The neoplasms which Pick examined were unmistakable epitheliomas of the thyroid gland. They occurred endemically in certain hatcheries among the same species and always at the same age, when the fish were over two years old. Sporadic cases also occur and wild salmon are also liable to be affected. The proportion of the brood affected ranged from 2 to 7 per cent. As the affection seems to be restricted to certain hatcheries in certain countries, and to certain species of fish in the hatchery, the local conditions must exert some influence in the matter. This throws light on the endemic character of cancer. The variability of the histologic findings recalls that of the epithelial tumors of the mamma in mice, and there is also a striking analogy between the trout cancers and malignant cancer of the thyroid in man. Pick does not think that the circumstances

indicate necessarily a parasitic origin for the growths. He is more inclined to admit that a primary, merely hyperplastic, strenuous proliferation of the thyroid gland, simple endemic goiter, in consequence of some external deleterious influence (possibly the composition of the water), causes a transformation of the originally harmless growth into malignant carcinoma. The article is profusely illustrated and continued to No. 49.

42. Injury of Eye from Paraffin Injections for Saddle-Nose.—Uthoff has had two experiences of this kind. In the first, embolism of the arteria centralis retinae developed immediately after injection of paraffin with a melting point of 43°C. It was the third injection, the two others having been made eight and five months before. He theorizes that the paraffin, still in a fluid state, must have passed into a vein and thence through the lungs and entered the arterial circulation, reaching the arteria centralis retinae in this way. In the second case a man of 57 had been successfully treated for saddle-nose, but after working in the garden on a very hot day a few months later he experienced a strange sensation in the eyelids and rubbed them. They swelled to such an extent that he was unable to open his eyes. Erysipelas was diagnosed at first, but excision of a scrap of lid tissue revealed that the trouble was inflammation from the presence of paraffin. In order to enable the patient to see at all, the large, hard, tumor-like masses which closed the eyelids completely were removed in several sittings, with the result that the patient is able to open his eyes enough to see. The inflammatory giant-cell proliferation in and around the droplets of paraffin was evidently the result of both the mechanical and the chemical action of the foreign body, the paraffin, which had found its way into the lids. Several somewhat similar cases have been published, but none in which the resulting disfigurement was so severe. He reviews the literature on the subject, citing several cases of blindness, and concludes with the warning not to inject too much paraffin at a time, and not to inject it in the centripetal direction of large venous tracts. He advises waiting a sufficiently long time before repeating the injections, to arrest the circulation in the adjacent blood vessels during the injection, and to use paraffin with a high melting point. Accidents have been reported after the use of hard paraffin, but they have not been so numerous or so severe as those after injection of paraffin with a low melting point.

44. Hypertrophied Prostate and Diabetes. Posner calls attention to the liability of overlooking an affection in the prostate when treating a diabetic patient. The prostate may be hypertrophied and cause disturbances which are credited to the diabetes, even during the periods when the patient has been freed from glycosuria. In other cases the pronounced hypertrophy of the prostate causes the physician to overlook impending or established diabetes. In his experience in the last ten months he has encountered 5 out of 20 cases of hypertrophied prostate in which unmistakable evidences of diabetes were found by searching for them. He is inclined to believe that the enlarged prostate has a distinct influence in predisposing to diabetes, as there is usually arteriosclerosis in such cases. He does not attribute the hypertrophy of the prostate to arteriosclerosis, but regards it as a new growth of a fibromatous or adenomatous nature. Persons thus affected are frequently arteriosclerotics, and there is certainly some connection between arteriosclerosis and diabetes. The slow healing and the course of wounds and the gangrene in diabetes are due to the affection of the smaller arteries. The frequency of sclerosis, calcification and atheroma in diabetes has long been noted. Treatment of hypertrophied prostate should, therefore, aim to ward off injurious influences from possible glycosuria. The repugnance to meat, characteristic of retention of urine, renders it difficult to feed such patients properly, and yet they have special need for a nourishing diet. The dangers of catheterization and of operative intervention are magnified by the presence of diabetes. Zuckerkindl lost a patient from diabetic coma after a successful prostatectomy.

51. Stimulation of the Cardiac Pneumogastric Nerve.—Rehnisch found in the course of much experimental and clinical research that stimulation of moderate intensity applied to the

cardiac pneumogastric nerve reduced the heart rate temporarily. The arrhythmia observed after febrile affections, in meningitis and in intestinal affections and in children is evidently due to irritation of the cardiac pneumogastric. He does not accept this as an expression of the affected heart itself, but rather as a reflex phenomenon.

53. Spondylitis Following Acute Infectious Diseases.—Fluss summarizes the conclusions derived from analysis of the cases on record, discussing the differential diagnosis, prognosis, treatment, etc. The importance of avoiding overexertion or a fall soon after an acute infectious disease is clearly demonstrated by the experiences related. Trauma certainly is a factor in the development of spondylitis after acute infectious diseases. Witzel even incriminates trauma in the bathing of typhoid patients as responsible for "typhoid spine" later. Every case of lumbago occurring after typhoid should be treated as if it were typhoid spine. Kuhn advises thorough examination of the spine from time to time after typhoid fever. Rest in bed is the main reliance in treatment. Moorehouse and Pallard and Taylor and Cannon have also found that rest in bed for three months proved successful after failure of all other measures. In severe cases, immobilization of the spine may be necessary besides the rest in bed. Quinke reports that a patient dismissed with a cast was almost completely cured by the end of a year. With immobilization, supplemented by cauterization and antiphlogistic measures, Bonardi cured his patients in 2 severe cases in sixteen and forty days. In a case reported by Schanz, the plaster bed banished immediately the intolerable pains. In four weeks a model for a leather corset could be taken and in two weeks more the patient was able to sit up and was cured by the end of the third month. Schanz insisted further that the corset must be worn regularly for a time and that the patient must sleep in the plaster bed. Rest in bed and antiphlogistic measures are sufficient only in the very mildest cases. He recommends placing the spine in the lordosis position as much as possible, as this best relieves the pain. In severe and threatening cases treatment should be active, as for tuberculous spondylitis. The physician should never rely on the spondylitis proving harmless. Newcome applied extension with an 8 pound weight in one case, curing the patient in a month. Quinke also applied extension in one case with improvement in six months, but the deformity persisted unmodified. Franke proclaims that all affections of the bones and joints after influenza demand extremely cautious treatment; irritation of the slightest kind, even gentle massage, is liable to aggravate the trouble beyond remedy in the acute and even in the chronic stage. Mercurial treatment is indicated at the slightest suspicion of lues. In only one of the cases on record was there necessity for incision and evacuation of pus. This was in a case occurring after influenza; the entire arch of the fourth thoracic vertebra was found decayed. Franke believes that the lesion heals under conservative better than under active measures. He obtained the best results from hot baths and hot applications. Drafts are particularly injurious during and after influenza. Sodium salicylate with an antipyretic was useful in the more acute cases. Some patients thought they were helped by ichthyol salve, others by very gentle massage with chloroform oil, especially during the later stages, but every careless pressure caused intense pain and aggravation of the trouble. The foremost indication is rest and protection of the affected part. The patients must be encouraged, as the trouble is so tedious that they early despair of complete recovery.

54. Torticollis.—Zesas concludes from his analysis of the published cases that treatment of muscular torticollis can not be schematic, but must be individualized to each case, with special regard to the duration of the affection, the changes in

the muscle and the resulting disturbances. In all cases seen early massage and orthopedic treatment should be tried first. Incision and division, not only of the shortened muscle but also of all the contracted cords, is the standard procedure. The after-treatment must be adequate, and in all severe cases and in case of relapse partial extirpation of the sternocleidomastoid with an eventual plastic operation on the muscle is indicated. In case of spasmodic torticollis, resection of the cervical nerves, especially when preceded by resection of the spinal accessory nerve, has given better results than division of the muscles. The operation is the more promising the fewer muscles are involved in the spasmodic contraction. Kalmns has collected 95 cases treated by operation. The results, although far from constantly successful, yet should encourage surgical intervention after failure of conservative measures.

55. Displacement of Trachea and Larynx.—Curschmann noticed that dilatation of the aorta sometimes pushed the trachea and larynx to one side. He found this displacement of the air passages also in a case of pneumothorax. It might serve to differentiate pneumothorax from a cavity in the lung. He has noticed also that a process of shriveling in the thorax is liable to pull the trachea over on the side affected. He gives illustrations of 2 cases of marked displacement from dilatation of the part of the aorta nearest to the trachea.

56. Consequences of Torsion of Appendices Epiploicae.—As mentioned in the editorial on page 124, Riedel has encountered a number of cases in which serious results had followed torsion of one of the small pouches of the peritoneum filled with fat, known as the appendices epiploicae. In six instances the torsion had resulted in the detaching of the end, the escaping fat then acting like a foreign body in the abdomen. He knows of only a single similar case on record. The serous inflammation resulting from torsion of an appendix epiploica resembles that observed in appendicitis. In one case the twisted pedicle of the appendix epiploica had constricted the small intestine to which it was adherent. In 2 other cases the appendix epiploica was included in a hernia. These cases demonstrate anew how extremely sensitive the omentum is to the slightest irritation. The reducible hernia had existed for years without disturbances, but pain developed at once when the included appendix epiploica became twisted. His first patient suffered from attacks of pain suggesting gallstones. No tumor could be detected by palpation. Adhesion of the gall-bladder was assumed, but the operation revealed merely two small foreign bodies of fat tissue loose in the abdominal cavity. They were nearly as large as cherries. The patient committed suicide three years afterward, and two other similar foreign fatty bodies were discovered loose in the abdomen. In another case an operation for assumed recurring appendicitis revealed merely a loose foreign body about 1.5 cm. long by .75 cm. thick. The symptoms in another case suggested gall-stone colic with icterus. Oil was given without effect. The gall-bladder was found soft and was removed, although there were no evidences of stones. Two fatty bodies were found lightly adherent to the transverse colon and a third loose on the meso-

colon, while a number of appendices hung by narrow pedicles from the colon. The symptoms in another case were chills and abdominal pain, watery and fecal vomiting. The only cause for the peritonitis that could be found on operating was a crescent-shaped appendix epiploica, with a loose, fat foreign body nearby, which had evidently escaped from it. The peritonitis continued its course and the patient succumbed forty-eight hours later. Micro-organisms resembling the colon bacilli were cultivated from the center of the foreign body. At the autopsy nothing pathologic could be detected in any organ to explain the peritonitis, aside from the fatty body that had escaped from the pouch of the appendix epiploica.

57. Mobilization of Scoliotic Spine by an Active Method.—Klapp has succeeded in transforming patients with scoliosis and weak backs into "back athletes," as he calls them. He develops the muscles of the back astonishingly and exercises the spine by a method which, he thinks, brings the muscles into play better than any conceivable apparatus. The patients are instructed to creep on the floor, the hand and knee on the same side close together or else stretched as far apart as possible. This is the ordinary four-footed gait exaggerated. As the patient takes a "step" he is instructed to stretch his hand as far forward and his foot as far backward as possible, drawing the hand and knee on the other side close together and at the same time looking back toward his foot on the concave side. He turns and looks backward on the other side as he takes the next step with the hand and foot on the opposite side. It is surprising, Klapp remarks, how the muscles of the back and pelvis are brought into play by these motions. They can be exaggerated still further by bringing the foot on the concave side across beneath the trunk and bending the extended arm toward the concave side. The hands and knees are protected by leather and the children think these exercises are great fun. The benefit is soon apparent. Before commencing the exercises superheated air is applied to the spine for twenty minutes to secure the mobilizing action of hyperemia. His contrivance for this purpose is a large box containing the source of the heat; the patients sit on stools, each with his back against a corresponding window in the box. In conclusion Klapp urges general practitioners to treat scoliosis in this way, especially after a course of orthopedic treatment, to confirm the results obtained. He does not weary the children by calling on them for any other exercises, reserving their strength exclusively for the creeping movements. The article is illustrated.

58. Congestive Hyperemia in Acute Inflammations.—Soon after Bier's revolutionary announcement that acute inflammation should be regarded not as something to be combated, but as one of Nature's curative processes which the physician should strive to promote, Küttner introduced the Bier technic into his clinic. The results of treatment on this principle of 105 patients with carbuncles, felon, phlegmons, infected wounds, lymphangitis and similar affections have converted him to an enthusiastic advocate of the new therapeutic congestive hyperemia. He calls it "the greatest therapeutic achievement of recent surgery." Its chief advantages, he says, are the doing away with the necessity for large incisions, with resulting scars, and for tamponing, while it reduces the length of treatment and prevents serious functional disturbances in joint and tendon sheath affections. It is indispensable, however, he adds, that Bier's directions should be closely followed, and that the application of the constricting band should always be closely supervised by the physician. It should never be left to the judgment of the patient or nurse. If medical surveillance is not possible, then this method of treatment should not be attempted. [Similar laudatory articles have appeared in many of our German exchanges. E. Guth states that the cessation of the pain is his criterion for the amount of constriction necessary to induce the proper dose of congestive hyperemia. He says that the relief is as great as from a generous injection of morphin, and that the method shortens the time of treatment and has the further advantage of reducing the danger from contamination of the physician's fingers with septic material. His experience with it in general practice is related in the *Prag. med. Wochf.* for January 18.—Ed.]

59. Treatment of Tonsillitis with Suction Apparatus.—Prym writes from Leo's clinic at Bonn to describe the excellent re-

sults attained in inflammatory affections of the tonsils by application of a suction apparatus to induce congestive hyperemia. The cup fits over the tonsil and is connected by a tube with the suction pump. No by-effects were noticed, except excessive secretion of saliva, during the application of the cup. He adds that it did not seem to distress the patients unduly.

63. Infants' Bath Tub.—At Escherich's clinic the infants sleep in an oval basket which fits into an iron standard. When the basket is lifted out, a sheet is laid over the oval frame of the standard, the ends tied below. A piece of rubber cloth is then laid over the sheet. A convenient and easily sterilized individual bath tub is thus provided for each infant. Or two wooden chairs can be placed with their seats together, facing each other, the legs tied together to prevent slipping. A sheet is then laid over the backs of the chairs and tied or held with safety-pins to form the bath tub, over which the sheet of rubber cloth is laid.

65. Negri Bodies in Diagnosis of Rabies.—This communication from the Catania Institute of Experimental Hygiene affirms the constant presence of the Negri bodies in animals with natural or experimental rabies. Materazzi is convinced that they are the specific causal agent of the disease. Inoculation of rabbits should never be omitted, as there is always a possibility that the suspected rabid animal may have been in that phase of the incubation when the saliva has acquired virulence, but the micro-organism has not reached the stage in its development when it proliferates in the cells. The search should be long and minute before proclaiming negative findings. Materazzi has never missed finding the Negri bodies. [In a communication from the Berlin Institute for Infectious Diseases, Bohne corroborates the specific value of the Negri bodies as a constant finding in rabies. It is published in the *Zeit. f. Hyg. und Infekt.*, xvi, No. 1. He found the bodies constantly in 200 brains and regards them as specific. He does not believe in their parasitic nature, as they are comparatively large, while rabies virus can pass through a filter. Another argument against their parasitic nature is that they are seldom found in the spinal cord and at other points where the tissues prove virulent when inoculated. The bodies seem to collect principally in the center of the hippocampus major. He has simplified Negri's technic and announces that his modified technic allows the discovery of the Negri bodies in three hours after receiving the material. This is extremely important when persons have been bitten by an animal which shows no other signs of rabies. The discovery of the Negri bodies settles the question as to the necessity for Pasteur treatment. His technic may be summarized as follows: Aetone for thirty to forty minutes; paraffin for sixty to seventy-

five minutes; imbedding, cutting into sections, mounting and drying; staining for one-half to four minutes with Mann's solution (35 c.c. of 1 per cent. aqueous solution of methylene blue and 35 c.c. of 1 per cent. solution of eosin, plus 100 c.c. of distilled water); brief rinsing in water; brief rinsing in absolute alcohol; absolute alcohol, plus solution of soda, for fifteen to twenty seconds; rinsing in absolute alcohol; water for one minute; water plus acetic acid for two minutes; rapid drying and imbedding. The Negri bodies were described in these columns on page 1490 of volume xlv. [—Ed.]

68. **Extirpation of Semilunar Ganglion.**—Pieri was unable to detect anything abnormal in 8 rabbits after removal of part of the celiac plexus. As soon as the wound had healed the animals were apparently in normal health for months afterward. The loss of the semilunar ganglion did not seem to have any influence on the weight of the animals. Methylene blue taken into the stomach passed into the urine just as promptly as in the sound animals.

69. **Nitrate of Silver in Pneumonia.**—Belfadel relates the histories of 24 patients with pneumonia treated with 15 cg. of silver nitrate daily. He remarks that the results were not such as to encourage its further use.

73. **Attitude in Asthma.**—In differentiating the various forms of asthma, Minervini lays great stress on the attitude during the attack. In bronchial asthma the patient gets up and goes toward a door or window seeking for air, supporting himself by a chair or window frame, retaining his sense of direction and coordination. If he can seize the back of a chair with both hands he clings to it, his shoulders raised and his body stooping forward. In cardiac asthma the patient is much weaker during an attack. He sinks into a chair or sits on the side of his bed, immovable, dumb, anxious, supporting himself with his hands on the seat of the chair or bed beside him. In uremic asthma the patient also assumes this position from lack of energy to rise, but he is much agitated and tosses his arms and legs about, the convulsive agitation sometimes passing into a rapidly fatal depression. He gives illustrations of the various types.

75. **Typhoid Gangrene.**—The robust young man whose case is described succumbed to the effects of gangrene of the leg, a complication of typhoid fever. He had injured his leg in a bicycle accident a week before the onset of the typhoid. It is possible that the trauma may have caused a place of lesser resistance in the artery where the typhoid bacillus set up the arteritis responsible for the fatal gangrene.

76. **Recent Progress in Therapeutics.**—Baccarani refers exclusively to Italy in his remarks. He congratulates his Italian confreres on the marked caution they have displayed in accepting and using the new drugs with which the markets are being constantly flooded. The tendency is constantly more apparent, he says, to return to the old, tried remedies of the pharmacopœia. "Why," he exclaims, "should we abandon the wealth of material which the long and continued experience of men, past-masters in the art of observing, has established as effectual? All we have to do is to go over the indications for their use with the aid of the lights of modern medical knowledge." In regard to organ therapy he thinks that results have not justified the high anticipations at first and that the subject requires much more study before it is definitely accepted that the extracts of certain organs are able to supplement the lacking, the exaggerated or the perverted internal secretions of certain organs. Vastly more encouraging is the outlook in what he calls "the new branch of the medical sciences, medical surgery." By this he means the close co-operation of the physician and surgeon in affections such as cirrhosis of the liver, nephritis, appendicitis, etc., and the therapeutic use of lumbar puncture. He says that serum treatment in the hands of the Italians has continued to give fine and durable results, as also the milk of immunized cows. Lucatello treats anemia with serum from animals previously treated with blood from anemias. Baccarani refers also to Bozzolo's successful treatment of leukemia with the x-rays, Tizzoni's encouraging experiences with radium in rabies and the continued success of Baccelli's intravenous injections of drugs in threatening conditions. The Italians have also confirmed the importance of salt in dropsical affec-

tions, restriction of salt tending invariably to reduce the effusions.

77. **Action of Formiates on the Circulation.**—Livierato was unable to discover any appreciable action on the heart or vessels from administration of formic acid or the formiates.

78. **Percussion of the Sternum.**—Landolfi has noticed increased resonance over the sternum when there is a cavity in the lung. When the resonance over the sternum persists as the patient reclines, but vanishes when he lies on one side, this can be accepted as a sign of hydrothorax or pyopneumothorax. Banti was the first to call attention to the retrosternal dullness observed in case of pleurisy with effusion, which aids in differentiating it from pneumonic lesions. Livierato affirms that the normal aorta does not alter the plessimetric findings over the sternum, but when the artery is dilated or altered by age there is dullness. The dullness becomes more pronounced as the trunk is bent forward. Enlargement of the right auricle is also liable to induce dullness.

86. **Tetanus and Subcutaneous Injections of Quinin.**—Grixoni reviews the various cases on record in which tetanus followed subcutaneous injection of gelatin, vaccine or quinin. He also relates experiences carried on at the Scuola d'Applicazione di Sanità Militare to determine whether tetanus germs can survive an ordinary solution of quinin. Tetanus spores are able to live in solutions of quinin, such as are currently used for subcutaneous injection, maintaining their vitality and virulence for a long time. Heating the solution to 105 C. for ten minutes or to 100 C. for twenty minutes always killed the spores in his tests. His further experiences disproved the assumption that injections of quinin have any influence on tetanogenic germs which may be present in the organism in the latent state. Fifteen years ago injections of quinin were comparatively rare, yet 615 deaths from tetanus occurred throughout Italy. The number has constantly declined, until last year there were only 250, and 162 of these patients were farm hands or stablemen. The military statistics have ceased to list tetanus, showing that there has been no mortality from this cause during the last few years, although the number of injections of quinin is now very large. The cases of tetanus observed after subcutaneous injection of quinin must have been due to contamination of the solution used, the germs finding a favorable soil for developing in the conditions produced by the injection of the quinin in a hypertonic solution. The reason that such accidents are not observed after injection of morphin, caffeine, strychnin, etc., is because these drugs do not cause anatomic changes at the point of the injection. When the quinin was dissolved in a physiologic saline solution no trouble of the kind has ever been observed. This assumption that the tetanus was the result of the development of the germs in the histological lesions produced at the point of the injection is sustained by the fact that quinin by the mouth has never displayed any general or local action in respect to tetanus. Grixoni refers frequently to Vincent's article, summarized in these columns on page 1646 of vol. xiv, 1905. He thinks that the results in Vincent's cases were due to the destructive changes induced by the concentrated solution which he used. The osmotic tension of the blood must have been violently disturbed.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A NEW TECHNIC FOR BREAST AMPUTATION.

JABEZ N. JACKSON, A.M., M.D.
KANSAS CITY, MO.

I wish briefly to present the description of a new technic for use in radical operations for carcinoma of the breast. I devised this method of operation about eight months ago, and since then I have used it exclusively in all cases of this character with which I have had to deal. From this experience, though limited to eight cases, I believe that the method has certain elements of advantage, as well as originality, that justify me in presenting it to the medical profession.

The skin incision in this operation is begun at a point about one and one-half inches below the middle of the clavicle, in the sulcus, marking the interval between the deltoid and the pectoralis major muscles. From this point the incision is carried in a straight line along the sulcus, parallel to the inner border of the deltoid muscle, until it reaches the lower border of the pectoral fold as it terminates in the arm. This straight incision is all that is made in this early step of the operation, but for the sake of clearness the complete incision is outlined here, that the general picture thus may be better obtained.

From the lower border of the first incision the knife is now carried along the under margin of the pectoral fold to the chest, at a point which corresponds, as a rule, with the lower border of the mamma itself. The remaining portion of the incision is made in the form of an ellipse about the nipple, with its long axis nearly vertical, or, rather, obliquely, from above downward and outward to the outer quadrant of the breast. This ellipse is so planned as practically to make its outer curve parallel with the line of the first incision made, and thus to present, when completed, a quadrilateral flap with its base upward and entirely free below. This incision, of course, is carried through the skin and fascia down to the underlying muscular structures (Fig. 1).

In the actual procedure, as before said, only the first incision is used in the early stages of the operation; but, if necessary to give greater space, a portion of the incision splitting the pectoral fold may likewise be made. As this incision is carried down through the skin and superficial fascia, it exposes the fibers of the pectoralis major muscle converging well to its tendinous insertion in the humerus. At the lower point of this incision, where it curves along the under border of the pectoralis major, the index finger of one hand is now shoved up underneath the pectoralis major muscle and brought out again at its upper border, so that the entire pectoralis muscle is thus hooked up on the index finger, and by blunt dissection separated out to its tendinous insertion. If, however, one wishes to follow the suggestion of Dr. C. H. Mayo and leave the clavicular portion of the pecto-

ralis muscle, this can easily be accomplished by bringing the finger up through the interval, usually well marked, between the clavicular and sternal portions of the muscle, and thus the clavicular portion can be separated and left in place. With the tendon of the pectoralis muscle thus lifted up, as shown in Figure 2, it is now divided by the scalpel very close to its insertion into the humerus. The muscle immediately retracts toward the chest and exposes, underneath, the pectoralis minor muscle invested

FIG. 1. Outline of skin incision complete, showing formation of flap A.

in its fascia, which above runs to the clavicle and below spreads out over the chest walls. This can easily be exposed by blunt dissection by the finger, which is now likewise inserted under the fibers of this muscle, which is now isolated as was the pectoralis major. It is also divided (Figure 3) close to its attachment to the coracoid process of the scapula. As to the pectoralis minor, like the pectoralis major, also retracts toward the chest,

the wound is held apart by retractors or by the fingers of an assistant, and the axillary space is now widely exposed to view from the front. As a rule this exposure can be made without encountering any bleeding vessels which will require clamp or ligature. Likewise we now have a wide exposure of the axilla for thorough dissection, without in any way having touched the breast or made any extensive division of tissues.

The axillary vein is now in view, and to its outer side and parallel to it, an incision is made with the scissors of the fascia which surrounds the vessels. The fascia is now stripped off, usually by blunt dissection and gauze, supplemented by an occasional snipping with scissors; the operator works steadily from without inward toward the chest, and clearing fascia, glands, etc., as he goes. In this way the axillary vein and artery are isolated, and the branches supplying the axilla and going on to the chest are made

Fig. 2 Division of pectoralis major muscle at insertion through primary vertical incision.

Fig. 3 Division of tendon of pectoralis minor at insertion.

plainly apparent (Figure 1). These vessels are at once double-clamped and divided between clamps. I have usually found it necessary thus to ligate about three or four sets of vessels. Time is saved by immediately ligating these vessels and then removing the clamps. Thereafter there will be no trouble with hemorrhage from the axilla, excepting, occasionally, from little veins in the cellular tissue further back toward the scapula or toward the chest. These incidental vessels, as a rule, will not be more than three or four in number and are usually ligated immediately after the clamping. Beginning thus at the apex and outer border of the axilla, fascia and glands are completely cleared by gauze and scissors dissection, working from the vessels inward toward the chest.

As this clearing of the deep axilla is completed, the

Fig. 4. Clearing fascia and glands from around axillary artery and veins, isolation at branches to fossa for primary ligature.

this is being done the breast is forcibly pulled back so as to expose the deep cavity of the wound. The pectoralis muscle is now severed from beneath, close to its points of bony attachment, and the perforating branches of the internal mammary which supply the vascularity of the breast are caught as soon as divided as they come through the chest wall (Figure 6). Usually two or three of these vessels will spurt, but they can be immediately caught with forceps and later tied. After the pectoralis major muscle has been entirely severed from beneath, the breast is allowed to drop back into its normal position, the skin incision is completed and the breast and the pectoral muscles underneath are finally clearly removed. Branches of the mammary artery which are clamped are now tied and the forceps removed.

Under these circumstances the skin incision practically does not bleed

original skin incision is also completed by carrying the horizontal incision over to the chest and marking the outer half of the ellipse so as to permit the flap to be raised and turned upward toward the clavicle (Figure 5), thus giving a deeper exposure of the attachments of the pectoralis muscle above and in front. It is important that a small tenaculum forceps should be placed at each angle of this flap when it is completed, as it will be of much service later on. The dissection is now completed usually with gauze, the tissues are loosened up underneath the pectoralis muscles under the breast and toward the chest. The point of attachment of the pectoralis minor to the ribs is cut from underneath, flush with the ribs and the costal muscles. From underneath the operator now loosens up the pectoralis major to its fixed points of origin from clavicle and sternum. While

Fig. 5. Flap completed and turned upward. Branches from axillary artery and vein ligated; dissection being continued from apex of axillary fossa downward and outward beneath retracted pectoral muscles.

at all, and it will be noticed that at no time during the operation were there more than a half-dozen clamps on the wound. As a matter of fact, the operation could easily be completed with from one-half dozen to one dozen clamps at the outside. This is made possible by the fact that all vessels are ligated as trunks at their points of origin instead of dealing with a large number of peripheral branches, as is usual in other operations. The extent of fascia dissected in this operation is the same as in any other thoroughly radical breast amputation.

The removal of infected tissue now being complete and the wound dry, the next step is to place the flap and close the wound; these also present points of distinct originality.

The quadrilateral flap of skin and superficial fascia which originally formed the anterior covering of the axilla is now stretched out

FIG. 6.—Axillary dissection completed. Division of pectoral muscles at origin from beneath. Mammary branches caught and ligated on division. Amputation completed.

FIG. 7.—Amputation completed. Flap A, the corners of which are held by tenacula, is drawn over to close the chest defect and the wound is closed by plastic adjustment. (The apparent laxity of the tissues is erroneous.)

by tenaculum forceps and transferred inward to cover the defect of the chest wall created by the removal of the skin of the breast about the nipple (Figure 7). This flap, which is one of the distinctive features of the operation, will always contract after it has been entirely loosened and will look as though it could be of but little service. A couple of tenaculum forceps in the angles, with probably another pair on either side, will spread it out until it covers a surprising amount of space.

As the flap is now drawn over on the chest, I usually fix it by attachment to the corresponding skin margin, as shown in Figures 7 and 8. Another distinctive point now consists in catching up, with the tenaculum, the margin of the lower portion of the pectoral fold, which represents the integument which formed the original floor of the axilla and which in thin

Fig. 8.—Flap in place and fixed by tenacula. Loose skin of original axillary flap drawn upward to complete covering and holding about axillary vessels, thus obliterating fossa axillaris.

subjects is often very marked. The tenaculum on this margin is placed at such a distance from the lowest point of the first vertical line that when drawn upward it will bring this skin point up to the original beginning of the first incision beneath the clavicle. This maneuver brings the loose skin from the floor of the axilla closely up around the axillary vessels and does away entirely with the axilla as a cavity in the subsequent anatomy of the individual. These tenacula likewise are usually clamped and mark these fixed points of contraction, as seen in Figure 8.

I generally now place an approximation suture of silkworm gut at these points to steady my subsequent suturing. The remaining portion of the incision may be closed either with interrupted or continuous sutures, as desired; or, as I have frequently done, by the use of subcuticular su-

tures of silkworm gut. It is most surprising, after the flap has been spread out and approximated properly under low tension there will be no suture line. Frequently the subcuticular stitches will suffice without the use of multiple sutures. A stab puncture in the lowest recesses of the wound space behind furnishes opportunity for drainage tube.

When the operation is completed (Figure 9) it will be observed that there is an appearance which has been likened to that of a clipper, with its handle running vertically along the inner border of the arm, paralleling the deltoid, the bowl of the cup being represented by three lines, each at right angles to the other, on the chest wall. There is thus no opportunity for linear contraction interfering with the function or utility of the arm.

This operation will be much better understood by reference to the illustra-

Fig. 9.—Suturing complete. Tension arteries at the base. Flap over the axilla.

tions which are represented herewith, and its advantages will be much more appreciated on practical trial.

In conclusion, I believe that this method has the following advantages:

First: The flap forms a covering for the chest defect, as a rule without any tension, and thus almost entirely obviates the necessity of grafting, which is so frequent in

Fig. 10.—Case 2. Picture taken two weeks after operation.

other methods. In fact, I have not found any patient operated on by my method who required grafting. Of course, this operation is not intended for cases in which

Fig. 12.—Case 4. Picture taken two weeks after operation.

Fig. 11.—Case 3. Picture taken four weeks after operation.

there has been extensive previous ulceration or in which there is not healthy tissue for a flap of any character.

Second: The drawing of the skin up to the arm does away with the axillary fossa, and thus with the large space which Nature would have to obliterate by formation of scar tissue, with the resultant pressure on the axillary vessels and nerves.

Fig. 13.—Case 5. Picture taken three weeks after operation. This patient shown at session of Western Surgical and Gynecological Association.

These first points are the ones which would probably be most striking to one who has not seen the operation.

Third: The ligation of all vessels at their nearest point of origin does away with the use of a large number of hemostatic forceps, which cause loss of time, to say nothing of the inconvenience of having a large num-

ber of instruments in one's way. I have in no instance used more than one dozen forceps in this operation, and can usually do the work with about six. The operation is thus shortened, so that, as a rule, I find that it requires from forty minutes to one hour or thereabouts to complete it. In fact, I have never run beyond an hour, even doing the operation slowly, as I have in most cases.

Fig. 14.—Case 7. Picture taken four weeks after operation.

for the purpose of demonstrating this new technic, and I have done the operation in forty minutes.

Fourth: The most noticeable feature to the onlooker, when the operation is done in the manner described, probably is the marked absence of hemorrhage, so that it can almost be called a bloodless operation.

Fifth: The entire technical portion of the operation is completed before the chest is exposed by removal of the breast; therefore long exposure of an enormous area of raw chest surface, with the attendant shock, is done away with. As soon, in fact, as the breast is removed the wound is ready to be closed.

REQUIREMENTS FOR A SUCCESSFUL CAREER IN SURGERY.*

LEWIS C. BOSHER, M.D.
RICHMOND, VA.

All of us can bear witness to the fact that to-day there are men engaged in the practice of surgery who, by reason of their lack of proper training, are thereby doing injustice to themselves, to the profession and to the public. Since there could be no greater mistake on the part of any young man than the selection of a specialty for which he lacks the necessary requirements, a general consideration of just what qualifications are needed as a basis for a successful career in surgery seems to me a subject worthy of discussion on this occasion.

So forcibly has this matter appealed to me for many years that very shortly after my election to this position I determined to take advantage of the opportunity of dealing with the subject on the present occasion, with the hope that my words, coming through this body of men, who are teachers of our great art, whose utterances are authoritative and whose precepts are accepted, might carry with them a certain amount of reflected authority and might serve to deter some at least from entering a field for which they are not equipped, and might even, perhaps, cause some others who are now rashly engaged in the so-called practice of surgery either to supply their deficiencies or to abandon the calling.

Although I had the privilege of hearing the oration of the chairman of the Section on Surgery and Anatomy of the American Medical Association at the Portland session, in which he treated the same subject in a most forceful, lucid and emphatic way, this seems to me no reason for abandoning my original intention, but rather a proof of the importance of the subject and an encouragement to follow up his opening, even though some similar thoughts may of necessity be dwelt on.

ATTRACTIVENESS OF SURGERY.

To the recent graduate in medicine no department of his chosen profession appeals with the same force as does surgery. While a student he has been impressed by the brilliancy of the results secured by his professors before his very eyes; at the meetings of the alumni the clinics in surgery have been crowded, while those in other branches have usually been either thinly attended or else attended as a compliment to the individual holding them rather than from actual interest in the subject; in most medical colleges the prominence of the professors of surgery in all faculty affairs is well known; while, considering the more material side of the question, he has little trouble in ascertaining that it is no unusual thing for a surgeon to secure for a single operation, occupying but an hour or two or even less, a fee greater than the entire collections of the general practitioner for a week's steady work, with broken rest and with cares and responsibilities innumerable. On leaving college, if he enters hospital service, those facts are impressed on him with even greater force; and later on, having himself entered the ranks of struggling practitioners, the same lessons are borne in on him with increasing emphasis.

Little wonder is it then that so many young medical men, bearing all these things in mind, decide that they, too, will enter this alluring field, where, they believe, they will effect such marvelous results, in brilliant cures, in abundant pecuniary reward, in the homage of their fellow-men, and, if moved by even higher motives, in the actual good they may do to suffering humanity.

These young men are all too prone to see but one side of the picture and to overlook the fact that here, as in all other pursuits, success comes only as the reward of special fitness.

The term surgery is still synonymous in the popular mind with cutting, and at once calls up visions of horrors of the operating room, with its rows of glistening instruments, the nauseating odor of the anesthetic, the insensible patient, and blood. Holding this view of surgery itself, surgical ability is commonly held to be identical with mere deftness of operative technic, while skill and promptness in diagnosis, the recognition of the possibilities of nonoperative measures, the power to distinguish between operative and nonoperative cases, the selection of the most suitable operation, judgment

* Presidential Address Southern Surgical and Gynecological Association, Dec. 12, 1905.

in knowing just how far to go—these and numberless other things of a similar nature, which constitute the real tests of surgical ability, are given little thought.

Were this failure to draw the correct distinction between the true surgeon and the mere skillful operator confined to the lay mind consideration of this subject on the present occasion would lose its point. But these same ideas, to a less exaggerated extent, it is true, find place in the minds of many of the young men for whose special benefit these remarks are intended.

PROFESSIONAL QUALIFICATIONS.

In a certain sense the preparation of the future surgeon may be said to begin before his birth, since blood will tell in surgery as elsewhere. Certainly the environment of very early life has a marked influence, for here the foundations of his character are laid, and even at this time there may be awakened in him a liking for the healing art which will have much to do with his selection of a career later on.

The importance of an academic education is too well recognized to require more than passing mention. Many a man has attained success in surgery without this advantage, but we are dealing with the rule, not the exceptions. This academic education should be truly liberal, both in quantity and quality, and should include as much as possible of studies of a scientific nature, especially biology, physics and chemistry. Of these three branches physics will prove of the greatest use to the surgeon, while biology and chemistry are branches of more practical value to the general practitioner. But the scientific habit of thought can not be too soon established, hence every study of this class is of service. At this time, too, will be laid the foundations of that general culture which will prove an invaluable possession in after life.

At the very beginning of his medical studies the best available school should be chosen. While at the medical college our future surgeon, no matter how firmly he may have decided on surgery as a career, should secure as thorough an all-round medical education as possible, not neglecting those branches which, as seems to him then, are not directly related to the practice of surgery. Only thus can he attain that breadth of view which will later on enable him to realize that the patients who come under his care are subject, in addition to the condition for which he is especially consulted, to the many other ills, both medical and surgical, which afflict mankind in general. Only thus can he appreciate the influence of mental conditions and gain an insight into the natural recuperative powers of the human system, both of which should be factors in influencing his decision as to the propriety of operating and in considering the question of post-operative recovery. Only thus, in short, can he hope to avoid the warping which is only too commonly seen in specialists in every branch, and which, so far as it relates to surgery, has given rise to the not altogether unjustifiable popular dread of consulting a surgeon, lest doing so should of necessity mean submitting to an operation.

After the completion of his course at the medical college a term of hospital service is nowadays considered an absolute essential. No matter what advantages the medical college has afforded in the way of clinics and opportunities for practical work, the newly-fledged doctor must learn in the school of actual experience. If he has real ability he will undoubtedly learn in private practice, but it will be only after many and costly mistakes, many of which may be avoided by proper hospital training.

In the matter of deciding what hospital he shall enter (providing it is with him a matter of choice) the personnel of the attending staff and the rules as to the duties of the house staff are the two points of chief importance. Service in the largest and most pretentious hospital under men of mere mediocrity and with improper discipline is far less to be desired than a position in a hospital where, perhaps, the cases are few, but are seen under a master, and where the interne's time is divided into terms of service in both the medical and surgical departments, in the order named if he aspires to enter the practice of surgery afterward. In the best hospitals to-day the new recruit occupies at first an entirely subordinate position, gradually being given more and more responsibility as he becomes qualified for it.

Having completed his term of hospital service, many young men find it to their advantage to undergo a still further apprenticeship as special assistant to some surgeon of prominence. This affords the opportunity to observe more intimately the methods of some single man of ability and is of further value in giving an insight into the manner of dealing with private patients, a knowledge of which often decides between success and failure.

What has been said of the necessity of other things besides mere operative ability must by no means be taken as minimizing the importance of the latter. The diagnosis having been made, and after the exercise of proper judgment in deciding as to the advisability of operating and as to what operation should be undertaken, the best surgeon is he who possesses the greatest operative skill. This, though perhaps the most easily acquired of all the accomplishments of the surgeon, demands longer experience. Here, too, as in the attaining of other acquirements, the time spent as hospital interne and as assistant to some able surgeon will prove invaluable. Daily observation of the methods of others who possess the operative ability he himself wishes to attain is a prime essential. Thus will he unconsciously become familiar, in a practical way, not only with the principal operations themselves, but also with the thousand minor details which are indispensable. He will, moreover, learn how to meet the many emergencies which inevitably arise during an operation and which demand prompt and decisive action, and he will have impressed on him the necessity of being ready at any stage of the operation, to modify the opinions formed beforehand, and, in consequence, similarly to modify the operative procedure, either in whole or in part. He will learn how to bring to bear that nice judgment in deciding, while operating, between those cases which will admit of the most deliberate, though never dallying, attention to the minutest detail and those in which it is imperative to keep the patient as short a time as possible on the table, even at the sacrifice of otherwise important details of the operation.

After this he will still have much to do before he is himself an able operator: for all things appear easy and simple when done by a master hand, and no amount of mere observation of the work of others can of itself make a good operator. Operations on the cadaver and on the lower animals are invaluable in conferring technical skill without any attendant risk to human life or well-being. Along with this he may undertake some of the simpler operations on the human subject, gradually advancing to those of greater difficulty in proportion as his experience in diagnosis becomes more extensive, his judgment more trustworthy, his eye and touch more practiced and his hand more steady.

During his entire hospital experience he will be constantly impressed with the fact that the possession of mere brilliant operative ability, unless combined with the other qualifications of a surgeon, may make a man a dangerous surgeon rather than a great one. For the same reason antiseptic and aseptic surgery, whose benefits to the human race can scarcely be overestimated, are not an unmixed blessing, for, by the very safety which they confer on surgical operations, they enable many men lacking the qualifications of a true surgeon to undertake capital operations with immunity from immediate ill consequences.

In connection with the value of the training as hospital interne a few words as to the general attitude of our young surgeon during this period of his career seem to me important. It is no uncommon thing to find even the newest recruit in hospital service undertaking to assume an importance utterly out of proportion to his ability, or, rather, in inverse proportion thereto. This is shown most prominently in the tone assumed in speaking of the members of the attending staff, finding expression not infrequently in actual criticism of his superiors in the presence of his fellow members of the house staff, before the nurses, and, not infrequently, before the patients themselves. Leaving out of discussion the woeful breach of professional ethics which such a course involves, these young men should realize that they can best secure the full advantages of their hospital training by confining their attention strictly to their own special duties. The really valuable assistant is he who does well the things falling in his proper domain. If he does these conscientiously he will have neither time nor inclination to indulge in meddlesome criticisms, and by doing his own part well he will not only inspire such confidence as will lead his superiors to entrust to him work of ever increasing importance, but he will gain insight into the responsibilities resting on a surgical assistant, which will stand him in good stead when he himself shall need help in this direction.

Having completed his college course and served his apprenticeship as hospital interne, and perhaps as special assistant, our young man is now ready to start off on his own responsibility. In some cases this step is made easy by his now being taken into partnership by the surgeon to whom he has acted assistant, but usually this is not the case, and at this time he casts off from his moorings and begins an independent career. And now, no matter how thorough his training, days of discouragement are likely to follow, days during which he may be further disheartened by seeing men of far inferior parts succeeding by means of tricks which he would scorn to employ or perhaps by means of some special pull. His attitude during this time should be that expressed in the words of Confucius, who said: "I will not be concerned at men's not knowing me; I will be concerned at my own want of ability." If he is all right in the last respect, gradually, with such work as will come his way (some of it from those who have all along been watching his career, and some of it thrown in his path by his former associates), and, especially, sustained by the knowledge of his own fitness and power to cope with whatever may come along, success will surely follow.

Most men at this stage of their careers find it necessary to take any kind of practice that offers. This is a fortunate state of affairs, since the same reasons which made it advisable for our young man to neglect no branch of his medical studies as a student now make it important for him to acquire that breadth of view which

is notably absent in the man who settles down too early in life to the exclusive practice of a specialty. As his work increases he may gradually find it possible and advisable to confine his attention more and more to surgery alone.

GENERAL QUALIFICATIONS.

Besides the special qualifications which have thus far been considered, it is scarcely necessary to do more than merely mention the many requirements of a general nature, which, while of essential importance in the development of the able surgeon, are of equal importance to success in any shape of life. Robust health, tireless energy, rigid honesty, temperate habits are requisites in any successful career. Attractive personality and abundant *savoir faire* are desirable here as in every calling in which one has much to do with one's fellow-men.

It may be confidently asserted that any young man equipped by nature and by training along the lines above laid down, and who has given careful thought to the selection of a proper field for his activities, may count on a reasonable measure of success as a surgeon. There are in our country to-day thousands of men who have thus risen to responsible position and who may be regarded as successful surgeons. Of these thousands, a considerable number have gone further and have come to be recognized as surgeons of prominence, while still others, a very few, have attained such eminence as to be recognized as the real leaders of our profession.

Will the means by which these last have reached their present position admit of successful analysis? Not to more than a limited extent; for here, as in all cases where we have to deal with true genius, there is an elusive something which ever eludes our grasp. Yet we can usually understand, in those instances which come under our immediate notice, somewhat of the factors which have contributed to the end. Unusual energy and determination, courage which never fails in the face of difficulties or even of temporary defeat, quickness of intellect in placing at their true value the results of the research of others, thus avoiding the error of being misled by attractive fallacies, while, at the same time, promptly seizing and applying discoveries of real value; boldness of initiative, never going to the extent of dangerous radicalism; broad views in dealing with one's patients, with one's fellow-practitioners, and with the world at large; and, lastly, that indefinable something which we call personal magnetism—these are among the factors which may serve to convert mere success into prominence.

A single small class of men may perhaps constitute an exception to all that has thus far been considered. In every lofty calling in life we find a few men—at times some of the very ablest of their profession—who apparently defy all the ordinary rules which apply to their fellows in the craft. And so, as in similar cases in other fields, we occasionally find men who seem to have been born surgeons, who with no apparent external advantages over even the least favored of their fellows—save such advantages as their own persistence, urged by unquenchable fire of ambition, has wrested from adverse environment—go on to achieve not only success, but distinction and fame. These are but the exceptions which prove the rule, and even to such men at the beginning of their career, the same advice should be given, since thereby the unfit man might be restrained from committing a fatal error, while he who has in him the fire of true genius will not be deterred by words of any man.

In conclusion, we must realize that this is a subject which concerns mankind in general; therefore, is it not

incumbent on us, as teachers and practitioners of surgery, to make it plain to the public that there is a material difference between the trained surgeon and the novice? This education will enable the public to discriminate in a wholesome manner and will ultimately have the effect of rendering it apparent to the candidate for surgical practice that he must properly equip himself before he can stand before the world as a representative of the great surgical art.

422 East Franklin Street.

A CRITICISM OF SOME OF THE THEORIES REGARDING THE ETIOLOGY OF GOUNDOU AND AINHIUM.*

F. C. WELLMAN, M.D.
BENGUELLA, WEST AFRICA.

My interest in the two rather bizarre tropical affections mentioned in the title of this paper has lately been increased by the opportunity of examining several cases of each disease. In reading over the views commonly held to account for their origin, one is struck by the fact that most of them are purely theories and, like most theories, not free from flaws. A short review of some of these may help to clarify what little knowledge we possess concerning the possible factors giving rise to the obscure conditions known as goundou and ainhiu.

GOUNDOU.

SYNONYMS.—*Anakhré* (Agni name), *Henpaye* (Gold Coast) *Gros nez*, *Mti* (Zanzibari), *Big Nose*, *Dog Nose*, *Ugubue* (Bantu name).

There have been proposed, among others, the following theories to explain the presence of the growths:

1. That they are a sequel of yaws (Chalmers).
2. That the condition is a disease *sui generis* (Bradford).
3. That the condition is an example of atavism referable to some tribal peculiarity of the original negro stock (Strachan).
4. That it is a manifestation of syphilis (Friedrichsen).
5. That the tumors consist of malformations due to non-union of the nasal and frontal bones (Keng).
6. That they are caused by the presence of larvae of insects in the nostrils (MacLaud).

The theory that goundou is a sequel of yaws has been put forward by Chalmers, Mell and others. My objections to it may be summarized as follows: (1) The only persons suffering from *uyuhue* (goundou) whom I have seen in Portuguese West Africa (two in number) denied ever having had yaws showed no traces of that disease and were from a district where yaws is almost unknown, a rare imported case being noticed only at long intervals. (2) The symmetrical double growth is against this explanation. (3) Its general geographical distribution does not agree with that of yaws. (4) According to reports, a much larger proportion of men than of women are affected, while in yaws both sexes are affected without distinction.

The second theory that it is a disease *sui generis* is really not an etiologic theory at all, as it attempts no explanation of the symptoms. If by the phrase is meant that goundou is due to a specific micro-organism, it is enough to reply that no such organism has been described.

Strachan's suggestion that the condition may be an instance of atavism is not reasonable in view of the fact that the structure of the tumor, according to those who have studied it most carefully, shows it to be the product of an inflammation. Strachan's observations were made, I believe, in the West Indies, and at least one of his cases was congenital.

The connection of goundou with syphilis is open to most of the objections against its identification with yaws.¹ In my own cases syphilis must be excluded, with the alternative of considering the two cases of goundou (which showed no other symptoms whatever) the only examples of that infection ever seen in an isolated interior bush tribe which I had under observation for several years. Another point is the fact that the coast tribes of southern Angola, among whom syphilis is rife, are no more subject to goundou than the people above mentioned.

The hypothesis advanced by Dr. Keng in the far East that goundou is a congenital malformation due to lack of union of the nasal and frontal bones is founded on the study of one case in which hydrocephalus developed with the tumors. A comparison of his description with my case notes leads me to believe that his case was not goundou at all. The facts that the tumors were soft and pulsating and painful when touched would alone distinguish them from the hard, bony, insensitive growths described by all observers in Africa.

MacLaud's original idea that the process is, in the first instance, set up by the presence of dipterous larvae in the nostrils has not been confirmed by the researches of later observers. Manson points out, too, that the symmetry of the growths is difficult to account for on this hypothesis.

It will be seen by this rapid résumé of ideas regarding the cause of the peculiar affection under consideration that none of the explanations proposed rest on anything more definite than conjecture. The tumors are doubtless a hyperplasia, probably due to an osteoplastic periostitis with a very definite cause which, however, has not yet been demonstrated.

AINHIUM.

SYNONYMS.—*Gudurum* (W. Africa) *Quijila* (Brazil), *Banko-Keréudé* (Soudan) *Sukha-pakla* (India) *Ecérese spontané*, *Esola*, *Ombanja* (Bantu names).

I shall consider in connection with this affection the following etiologic theories:

1. That ainhiu is a lesion of leprosy (Zambaco).
2. That it is caused by injuries to the toes (da Silva Lima).
3. That it is due to a trophoneurosis (Scheube).
4. That it is a circumscribed scleroderma (Corre).
5. That it is a congenital spontaneous amputation (Proust).
6. That it is the result of self-mutilation by ligatures, the wearing of toe rings, etc. (Gongora and others).

As to the first hypothesis, I have several times lately seen the suggestion that ainhiu may be a manifestation of leprosy. Some of these communications enter into the question with considerable definiteness, and in one instance several cases are cited in which all of the patients are reported to have had leprosy parents or relatives and to have evinced signs of leprosy aside from ainhiu. All this is, of course, Zambaco Pasha *rediri-*

* Published under the auspices of the American Society of Tropical Medicine.

1. I do not here enter into the discussion of the identity of yaws and syphilis as maintained by Hutchinson, and more recently by Scheube in his "Die venerischen Krankheiten in der warmen Lnder," p. 51. For the purposes of this paper the clinical manifestations as seen in typical cases quite suffice.

cus. This observer brought to the study of the question an unusually wide and accurate knowledge of leprosy, but seemed to have acquired a habit of annexing various complaints in order to bring them into line with his specialty. An instance in point is his contention that Morvan's disease in Brittany is only a mild form of leprosy, the virus having become attenuated through the isolation of a comparative old population. The identification of Morvan's disease as a form of syringomyelia did not, however, deter Zambaco from later claiming ainum, on theoretical grounds alone, as another example of attenuated leprosy. The question which Zambaco proposed to himself may be stated in the words which form the title of his communication to the Academy of Medicine in July, 1896: "*L'ainum des auteurs, constitue-t-il une entité morbide distincte, ou bien n'est-il qu'une modalité de la lépre?*" and the verdict enunciated was "*L'ainum des nègres. . . est une lépre légère, monosymptomatique, dactylienne podique, c'est-à-dire mutilante des pieds.*" Such a conclusion is, of course, permissible from the hypothetical side, but on clinical grounds alone it should be remembered that the ainum-like constrictions sometimes seen in leprosy nearly always affect the fingers and are always connected with other symptoms of leprosy. One could wish, however, that the question had been approached from the pathologic standpoint. The bacillus of leprosy has been found in every tissue of the human body, except the muscles, and has a special predilection for the skin. It would certainly seem fair, then, to demand a demonstration of this bacillus in at least a few of the cases exploited as *Lepre ainoide*. The fact that the geographical distribution of leprosy and ainum (to say nothing of the racial distribution of the latter) does not coincide detracts, too, from the force of Zambaco's theory, which later authorities seem to adopt on the strength of his name and in connection with it carefully to shun any reference to *B. lepro* or other features which may be rigidly tested by scientific methods.

In this region, leprosy is not uncommon, while ainum is comparatively rare. I have collected three cases, however, concerning which I have recently published a note containing the following observations:

1. In none of these cases is there a leprosy lesion demonstrable.
2. In none of these cases is the characteristic facies familiar to those who are acquainted with negro leprosy present, nor are there any of the other early clinical symptoms of leprosy.
3. In none of the three cases is there a family history of leprosy (I have seen the parents of two of the men and the father and grandfather of the third).
4. Only one of the patients comes from a district in which leprosy is known to exist.
5. In none of the cases can *B. lepro* be demonstrated in the nasal discharge by Ziel-Neelsen's method, and in one case in which I had amputated the offending toe no bacilli could be seen in a section of the integument from the constricted portion stained after the same method. The histologic architecture, too, is different from that of leprosy, showing only the familiar fibrosis and atrophy common to all cicatricial tissue.

Consequently, I must agree with de Bruin (who reported the case on which Zambaco based his opinion above quoted) that "*L'absence, dans les cas d'ainum, du bacille de Hansen, semble démontrer qu'il ne s'agit pas d'une manifestation lépreuse.*"

The hypothesis originally put forth by da Silva Lima to account for the lesions was that the toes are cut by sharp grasses and the like, and the contracting cicatrix produces the condition as usually described. In opposi-

tion to this theory is the fact that the ailment has been noticed in negroes who usually wear shoes. But, as Manson remarks, "unless it could be shown that such individuals had always worn shoes this objection to the explanation offered would not apply." Another objection to da Silva Lima's theory is that the disease does not occur equally in all barefooted races. Even in Africa the geographical distribution is capricious. Again, it is stated that in Brazil ainum is becoming less common among the negroes who nevertheless go barefooted as in former days.

Scheube's suggestion that the lesions are the result of a trophonurosis makes no attempt to explain the origin of the condition. Such a theory is in the nature of a *tertium quid*, and only puts the difficulty one step farther back.

The view of Corre and Despitets that ainum is a circumscribed scleroderma is open to the same criticism. Scleroderma is an induration of the skin largely due to hyperplasia of the connective tissue and muscle fibers of the corium. Its etiology is not known, although it has been connected with disease of the thyroid gland. It has also been described as following acute diseases and exposure. The local nature of the lesion in ainum does not accord well with these views. The thyroid glands in the three patients I examined were apparently normal.

An idea advocated by some (principally by Proust) is that we have to do with amputations which come about by constrictions of amniotic filaments during fetal life. Scheube well urges against this view the facts that such amputations "are congenital and occur on various parts of the body; they are not limited to the toes, are generally multiple and frequently occur simultaneously with other deformities; they, therefore, differ essentially from ainum."

The wearing of rings on the toes can hardly be seriously entertained as a cause. In the first place, one never sees or reads of rings worn by African natives on the little toes alone. Again, few tribes wear rings on the toes at all, and if the wearing of rings caused the affection the hands would be affected oftener than the feet. The statement that ainum is self-mutilation through tying strings lightly around the toes is groundless and has not been confirmed.

In conclusion, the above review teaches us that no definite and undisputed cause for the lesion has been advanced. I think that there is most to be said in favor of da Silva Lima's theory. Manson puts the case to the best advantage when he suggests that the condition "is provoked, at all events in the first instance, by wounds so easily inflicted on bare feet in walking through grass or jungle. The fold of skin in which the lesion of ainum commences is very liable, especially in the splayed-out toes of the negro, to be wounded in this way. If we examine the under surface of the joint flexures of the toes in many individuals of this race, even in those not affected with ainum, we often find the skin, particularly at the proximal joint of the little toe, thick, rough, scaling and sometimes even ulcerated. One can understand that continual irritation of this sort, produced and kept up by wounds from sharp grasses, would in time give rise, especially in the dark-skinned races so prone to keloid, to fibrotic changes in the derma, which might very well end in a sort of linear cicatricial contraction and ultimately in slow atrophying strangulation of the affected member."

I would insist that the groove around the toe in this

affection is, both macroscopically and histologically, a cicatrix. A probable factor in the prolonging of the irritations and inflammations set up by wounds and bruises at this point (which I have never seen mentioned by any writer on the subject) is the chigger, *S. penetrans*, which seems to have a predilection for this particular spot, especially if, as is so often the case, the skin be cut or torn. As to the fatty and atrophic changes in the amputated toe I use the words of McFarland, that their "true cause is not determined; it may be trophic or it may depend on local cicatricial formations."

TUBERCULOSIS AND PATENT MEDICINES.

G. R. POGUE, M.D.
DENVER, COLO.

Since the beginning of the present campaign against tuberculosis a vast amount of literature bearing on the subject of preventive measures and cure in regard to the disease has been distributed among the laity. Besides what has been distributed by those desiring to educate the public, numerous articles have appeared in magazines. Almost every writer dwells on the point that there is no medical cure for tuberculosis and everything is laid aside for the so-called outdoor treatment, which all admit is the most important part of the treatment for tuberculosis when properly administered.

In our anxiety to educate the public on the subject we overlook the result of our therapeutic nihilistic statements, which often leaves the poor victim of tuberculosis convinced that a physician can give him no aid, as it has been acknowledged that there is no cure for consumption. In his fight for life and health he naturally turns to those who "promise" him relief. He eagerly reads every advertisement that comes his way, and tries one "remedy" after another, for, with the consumptive, while there is life there is hope. We do not have to go far to see the results. When one shark has got all the money he can out of the victim another is ready to pounce on to him with a "new cure." In this way a great percentage of the vast army of tuberculous patients becomes a revenue to the "patent-medicine" shark and the advertising quack, with his "sure-cure" and fake testimonials. That percentage is increasing every day through our means of false education, and the advice of the attending physician is set at naught, because patients have been pre-educated and taught the false doctrine that outdoor life is all that is required and "the doctor can do nothing to help cure consumption."

During a conversation recently with a prominent pharmacist he made the statement that sales in patent medicines had fallen off 50 per cent. in the last three months, and incidentally remarked that he seldom sold certain preparations except to consumptives. "They will drink any old thing so long as it is advertised to cure consumption." Now, on the one hand, we are endeavoring to educate the public in regard to the dangers of patent medicines and their uselessness, while, on the other, in trying to educate the masses as to the dangers of spreading infection and the best means to cure a certain disease, we are driving a certain class of individuals into the folds of the "patent-medicine" vendor and the advertising quack.

To be sure, we have no specific remedy for tuberculosis to the exclusion of every other remedy or measure. Nor have we for any other disease. What would be the

result in a case of tetanus were we to rely on a few injections of tetanus antitoxin without a knowledge of its action and how to use it in the different stages of the disease or in suspected tetanus infection? What would be the mortality in diphtheria were we to simply administer a dose of diphtheria antitoxin and then leave the patient to do as he deemed proper? Antitoxin has a specific action in diphtheria, but notice the anxiety of the attending physician and the special care he takes of his patient for several days, watching for the various complications which may occur; ready to check them if they appear.

Other acute diseases, such as pneumonia and typhoid fever, are caused by micro-organisms, and we have no specific remedy for them, but we do not preach broadcast over the land that there is no medical aid that can be given to patients suffering from such diseases. That these individuals require the care and advice of skilled physicians is a fact that none will dispute.

Tuberculosis is a slow disease, often requiring years to destroy its victims. It is also a disease with a tendency to recovery, if recognized early and properly handled, and during its long course the patient needs the advice and care of the skilled physician until the disease is arrested, and then supervision is required for some time after.

What does a layman suffering from tuberculosis know about recurrences, aspiration pneumonia, pleurisy with effusion, empyema, etc.? He does know that when certain of these conditions occur in the course of his disease, that he feels worse, and, if he be one who has lost faith in his physician through our newer education, he straight way goes and "fills up" on some dope containing opium or alcohol, perhaps both. We all know the results.

Climatic resorts to which consumptives flock seeking a return to health are a bonanza for the advertising quack and "patent-medicine" vendor. The stock argument of these sharks is that members of the medical profession have no cure for tuberculosis, and that physicians acknowledge this, while each of these "quacks" claims to have some "great" secret remedy discovered by some "eminent" man and that it is a "sure cure." The poor consumptive is only too ready to grasp at any help that may be offered him, and in the present condition of things these are the only men who "offer" anything, so far as a great many of the public see.

The high percentage of "cures" or arrested cases in sanatoria does not depend on the patient getting better air or nourishment than can be had elsewhere, but on the constant supervision of the patients by skilled physicians and the proper administration of therapeutic measures suited to the requirements of the individual patient.

Up to the present time only a small percentage of those suffering from tuberculosis have been treated in sanatoria in this country, and the balance are scattered over our broad land in all conditions and stages of the disease, numbers of them vainly hunting for some one to hold out a hope of relief. Is it any great wonder that the uneducated or falsely educated easily fall a prey to the advertising quack?

It would be well for the community at large if some of our therapeutic nihilists would turn their talents in some other direction, and, if they wish to write for the education of the laity, write on some subject which the laity may understand and be benefited thereby.

The medical profession, as a whole, is an educated body and will eventually work out the therapeutics of tuberculosis, as it has in other diseases. In the mean-

time individual physicians will use the knowledge and skill they possess, as they have always done, for the welfare of their tuberculous patients and the community at large, teaching hygiene and prophylaxis and guiding their patients to renewed health.

SURGICAL REPAIR OF INJURED NERVES.*

J. SHELTON HORSLEY, M.D.

Professor of Principles of Surgery in the Medical College of Virginia; Surgeon to Memorial Hospital.

RICHMOND, VA.

The principles of nerve suture are so intimately connected with degeneration and regeneration of peripheral nerves that a brief review of the histologic process involved may not be inappropriate. The method of regeneration of a mixed nerve has been the subject of much discussion, and even now there is no view that receives the general sanction of neurologists. The Wallerian or continuous theory, which claims that regeneration of the axis cylinder occurs from the central stump only, is being somewhat discredited. Recent researches tend to confirm the discontinuous theory or some of its modifications. Huber and Howell, in 1892, and later Behe of Strassburg, have shown quite definitely by numerous experiments that in young animals regeneration of an injured nerve may be practically complete without any connection with the central end. In older animals regeneration without connection with the central stump also occurs, but is imperfect. Schütte,¹ after an exhaustive review of the literature, corroborates this and maintains that degeneration always occurs after division of a nerve, no matter how accurate the approximation or clean the wound, though degeneration and regeneration may proceed simultaneously. As would be expected, the destructive effect of suppuration increases degeneration in the central end. While Schütte concludes that central connection is not necessary to regeneration in a peripheral nerve, it is true that such connection with the so-called trophic center must sooner or later be made in order to preserve the nerve in a healthy condition. Of course, there can be no physiologic function without this, no matter how perfect the anatomic repair may be. It is also true that regeneration is more prompt and more nearly perfect when the peripheral and the central ends are united than when they are separate.

It has been shown by a number of investigators that if a severed regenerated nerve is again cut, degeneration will take place in the distal segment, but the segment between the first and second cuts will not degenerate to any marked extent, though it has been entirely separated both from the cord and the peripheral segment. There seems to be no satisfactory explanation of this phenomenon, but its occurrence shows that neither the ganglionic cells of the spinal cord nor the peripheral nerve endings are essential to regeneration—a fact that might prove valuable where there had been multiple injuries along the course of a nerve.

In view of the constant degeneration of the peripheral segment of a divided nerve, it is somewhat difficult to explain the early return of function in many cases. Thus, Victor Horsley² mentions a case of suture of the ulnar nerve followed in twenty-four hours by return of

sensation in the little finger. Peterson³ reports a case in which the sciatic nerves of a dog were used to bridge a defect in the ulnar and median nerves in man with return of sensation the day after the operation. Two weeks after the operation, sensation was almost complete and the natural color of the hand was restored. There are many other reported cases following a somewhat similar course. Victor Horsley says they may be explained as follows: If a nerve is cut and the freshly divided ends are united, two extensible masses of nerve protoplasm are brought into contact, and one may conduct stimulating impulses from the other just as when two freshly divided pieces of muscle are fixed together; excitement of one piece will produce contraction of the second by transmission of the electric energy which caused contraction of the first piece. For a few days after suture of a nerve the excitability of the nerve protoplasm remains active, then it gradually disappears as a rule, though occasionally it is permanent.

SYMPTOMS.

The symptoms of an injured nerve depend to some extent on the character of the injury. Complete aseptic division of a mixed nerve results in abolition of motion and sensation in the area supplied by this nerve and in simple atrophy, but no trophic disturbance, such as glossy skin or blebs, results. If, however, the lesion is an irritating one, trophic symptoms may appear, though the destruction of the nerve is only partial. Such disturbances occur after suppurative involving a nerve, or the gradual encroachment of a tumor or callus, or after constant pressure from a dense cicatrix. Pain is not present if the destruction of the nerve is complete and of a non-irritating nature. When the whole nerve is not severed, or if the lesion is of an irritating nature, pain may be severe and is due to the abundant supply of sensory nerves to the nerve sheath, which are not only excited by the injury, but stretched by the resulting vasomotor paralysis along the nerve. Electrical reactions, either galvanic or faradic, depend on the ability of the nerve to functionate to some extent. A nerve that has completely degenerated can no more convey electrical stimulation than could a fibrous cord, yet the fact that such stimulation fails to produce a contraction does not necessarily mean the complete absence of all nerve fibers, for some may exist, yet be so few in number and so feeble in conducting power as to produce no appreciable reaction.

TIME OF OPERATION.

The time which should elapse after traumatic paralysis of a nerve before operation for its relief is a question of much importance. B. Sachs⁴ says three and a half months after facial palsy is too soon to consider operation. Dr. Hammond mentioned the case of a boy who developed facial palsy after a mastoid operation, and, without any attempt at nerve suturing, motion in the affected muscle was first noticed 15 months later. Henrikson⁵ thinks it unwise to wait over a month if there is no improvement. Others advise waiting as long as 18 months before operating. Much depends on the character of the injury. If the nerve has been divided by a clean cut, as after a stab wound, and primary union has resulted, the surgeon would be justified in waiting 12 or 18 months for the normal functions to return; but if the injury was a crush, or if suppuration resulted,

5. *Lancet*, April 18, 1903.

two or three months should be all the time allowed to elapse without improvement. When there is compression, as from callus or a tumor, operation should be performed at once. No operation for nerve suture should be abandoned because of the length of time that may have elapsed since the trauma. While regeneration and good functional results are more liable to occur when there have been only a few months from the time of the injury to the date of operation, still a number of successful cases are reported where many years have elapsed since the injury. For instance, Brenner⁶ records a case in which successful suturing was done on the median nerve 10 years after the original injury.

METHODS OF OPERATING.

Before mentioning the different procedures used for the repair of defects in nerves, it may be well to call attention to the statement of Bowlby⁷ that the function of some nerves in the same individual is restored more readily than that of others. He says better results are obtained after suture of the peroneal or the musculo-

spiral nerve than after suturing either the median or the ulnar. If this be true it would not be accurate to compare results following one method of operating on the musculo-spiral, for instance, with a different method employed on the median, as the same operation that succeeded in the nerve whose function was easily restored might fail in a nerve more difficult of repair. The greater danger of suppuration following its introduction and the interference with the nutrition of the nerve are serious objections.

2. *Flap Operation.*—Flap operations consist of splitting from one or both ends of the nerve sufficiently long flaps to bridge the defect and suturing them together. There are a few successful cases reported, though this method is not popular, as too much healthy nerve tissue is sacrificed in making the flaps. Most of these operations have failed.

3. *Nerve Bridging.*—The term "nerve bridging" may be applied to that class of operations in which some for-

Fig. 1.—Taken January, 1905, about two weeks after the second operation and fourteen months after the first. This photograph shows the scar over the musculo-spiral and the hand flexed as far as possible at that time.

spiral nerve than after suturing either the median or the ulnar. If this be true it would not be accurate to compare results following one method of operating on the musculo-spiral, for instance, with a different method employed on the median, as the same operation that succeeded in the nerve whose function was easily restored might fail in a nerve more difficult of repair.

The surgical methods of repairing nerve defects may be classed as follows: 1. Simple suture. 2. Flap operation. 3. Nerve bridging. 4. Nerve implantation or anastomosis.

1. *Simple Suture.*—Under the head of suture are included not only those cases in which the ordinary technic of freshening the ends of the nerve and approximating them with fine sutures into the nerve substance and into the sheath is employed, but also cases in which other procedures are necessary to facilitate this approxi-

Fig. 2.—Taken January, 1905, about two weeks after the second operation and fourteen months after the first. Note the dull and crumpled appearance of the nails of the index and middle fingers as compared with the other nails; also the enlarged and glossy appearance of the distal joint and the last two phalanges of both of these fingers.

mate substance is used to bridge the defect between the two ends of a divided nerve. Dr. Powers, in a most interesting article,⁸ reports a case in which he filled the defect in the external popliteal nerve of a man by transplanting four inches of the sciatic of a dog. The nerve was taken from the dog and immediately transplanted. The wound healed primarily, and 45 days later all forms of sensation were reported normal, but the muscles supplied by this nerve would not react to the strongest faradic current. Eight years after the operation, sensation over the region normally supplied by the peroneal had practically disappeared and the muscles remained entirely paralyzed. Powers has collected from the literature 21 cases in which nerve tissue from a lower

animal was used to correct defects in a human nerve, and of these cases only 21 per cent. may be said to have terminated in a satisfactory way. He concludes that nerve bridging or transplanting should be discarded.

The nerve tissue transplanted from lower animals in all probability has no intrinsic value in repairing defects in human nerves, but merely serves as an organized tissue would under similar conditions in providing a path for the growing nerve fibers to follow, so protecting them from the surrounding tissues. The suture *à distance*, where several strands of catgut connect the ends of a nerve, involves exactly the same process and should be included under this head.

4. *Nerve Implantation or Anastomosis.*—The term "nerve implantation" may be applied to operations in which the peripheral and the central portion of an injured nerve are implanted into a neighboring healthy nerve, or in which the peripheral end only is so implanted. While nerve implantation has not been performed so frequently as nerve bridging, the results have been more encouraging, the proportion of successes being about 50 per cent. I do not include those operations for correction of deformities following such diseases as infantile paralysis, where the lesion is in the spinal cord and the nerve fibers are secondarily involved through their whole extent, but merely those cases where there has been some local injury to a peripheral nerve. Be-

Fig. 3.—Taken Nov. 16, 1905, about ten months after the second operation and two years after the first. Nails of index and middle fingers are short from loss of substance at tips of these fingers from previous ulceration, but are smooth and of normal color. Size and appearance of distal joints and phalanges of these fingers are about normal.

sides the clinical evidence, a number of experiments have demonstrated the feasibility of such an operation as implantation. In an experiment by Spitzzy,¹¹ the peroneal nerve was grafted onto the tibial. The clinical results were good, and microscopic examination of the site of the grafting plainly showed the passage of fibers from the tibial nerve into the implanted distal portion of the peroneal. As between the last two methods of correcting defects in nerves (that is, nerve bridging and nerve implantation), a study of the literature on this subject, both from an experimental and a clinical standpoint, seems to show the superiority of nerve implantation.

The following case of nerve implantation may be of interest both from a surgical and an anatomic standpoint:

Patient.—H. J., aged 21 years, was kindly referred to me by Dr. George Ben Johnston. He was a large, muscular negro, whose previous health had been good. Family history was of no significance.

History.—In August, 1903, he was thrown some distance by the explosion of a boiler. There was a fracture of the leg, a scalp wound and a severe trauma to the soft parts of the upper right arm. The bone was not fractured, nor was the shoulder dislocated, and the skin was only broken at a small place on the outer side of the arm. He was unconscious for several hours, but on recovering consciousness found his right hand and forearm paralyzed.

Examination.—Nov. 17, 1903, he came under my care. His other injuries were nearly well, but so far as could be made out complete paralysis of both sensation and motion existed in all of the forearm and hand except in those muscles supplied by the ulnar nerve and that portion of the skin supplied by the ulnar and the musculocutaneous nerves. In the upper arm the action of the triceps was unimpaired, but flexion was weak. Besides marked atrophy no trophic disturbances were present.

Operation.—An incision was made over the upper part of the

Fig. 4.—Taken Nov. 16, 1905, about ten months after the second operation and two years after the first. Note good flexion of fingers and hand; also slight keloid development at scar over the median at the last operation. Just above this is part of the scar of the first operation.

course of the median nerve. The upper brachial artery was obliterated and no trace of the median nerve could be found. In the place of the nerve and artery was an indistinguishable fibrous mass. The ulnar nerve was normal. After extending the incision down to the middle of the arm the median nerve was found. It was in fairly good condition here, but the line of demarcation between healthy nerve tissue and an absolute fibrous cord was quite sharp and distinct. The median from its origin for a distance of two and one-half inches had been completely crushed and its sheath, with the remains of the brachial artery, formed a fibrous mass, in which no trace of nerve tissue could be found. It was impossible to stretch the nerve or to form a flap to bridge such a defect, so implantation into the ulnar was done. The median was cut almost across half an inch below the point where it first appeared healthy and the peripheral end sutured into a nick in the ulnar. A fine needle and fine chronic catgut were used, one suture being put into

11. Amer. Jour. of Orthopedic Surgery, August, 1904.

the nerve substance and several into the sheaths of the ulnar and median. Care was taken not to tie the sutures too tightly. The median was not cut entirely across, a few fibers and the outer part of the sheath being left, as they served to hold the nerve to the fibrous mass just above it and thus relieved some of the tension on the sutures. From the fact that the triceps was unimpaired, the injury to the musculo-spiral must have been lower down, so no attempt was made to find it and the wound was closed. Union was by first intention. The patient left the hospital two weeks after the operation. He reported later that improvement in motion and sensation began within a month after the operation. As he was not very intelligent it was difficult to get an accurate account of the progress of improvement, but it was evidently quite rapid after this time.

Further History.—On Jan. 15, 1905, he returned to the hospital. Flexion of all the fingers was present, though much stronger in the little and ring fingers than in the others. The thumb could be flexed or adducted as a whole, but chiefly from the carpo-metacarpal joint. The last phalanx could be flexed on the first very slightly. Much to my surprise, extension was present in the hand and all of the fingers and the thumb, and had evidently improved along with flexion. The probable cause of this will be discussed later. Sensation to pain and touch was present over the palm of the hand and palmar surfaces of the fingers and thumb, though over the ulnar side it was prompt and normal, while retarded and less acute over the region supplied by the median. Sensation to touch and pain was present over the whole forearm, though somewhat impaired over the back of the forearm and back of the hand, except to the ulnar side of the back of the hand and forearm, which was normal. Sensation over the back of the little finger was satisfactory and was also present on the back of the thumb and the ring finger, though not so marked. There was complete anesthesia over the backs of both the index and middle fingers from the roots of the nails to near the metacarpophalangeal joint, where it gradually blended into very much impaired and retarded sensation over this portion of the back of the hand. One of the remarkable features was the presence of trophic disturbances in the nails of the index and middle fingers. About four months after the operation ulcers appeared on the tips of these fingers and refused to heal entirely; at the same time the nails became crumpled. This condition is shown in the photograph taken January, 1905. There had been no injury to these fingers. No affection of this character was present at the time of the operation in November, 1903.

Second Operation.—A second operation was done on Jan. 17, 1905. Both operations were performed at my clinic at the Memorial Hospital, Dr. H. H. Levy, emeritus professor of medicine in the Medical College of Virginia, and Dr. J. W. Sonthal being present, in addition to the students, at the last one. A short incision just above the elbow exposed the median nerve, which appeared normal. The musculo-spiral was then exposed to the outer side of the elbow, where it lies between the brachialis anticus and supinator longus. It was small and yellow and presented distinct evidences of marked degeneration. This nerve was followed up the arm for three inches, where it was cut across and a fine silk suture inserted. With a closed hemostatic forceps an opening was burrowed beneath the biceps from the lower angle of the incision exposing the median to the lower angle of the incision over the musculo-spiral. The forceps then seized the suture previously placed in the musculo-spiral and so drew this nerve to the median. A slight nick was made in the median and the musculo-spiral was implanted with fine sutures of chromic catgut in the same manner as the median had been implanted previously. The wounds healed by first intention. The operation did not interfere with the motion of the hand or fingers, with the exception of apparently somewhat lessening the flexion of the thumb, which may have been caused by the slight nick in the median.

Postoperative History.—On Nov. 16, 1905, the patient reported for examination. He was greatly improved in every respect. The trophic disturbance of the index and middle fingers had disappeared and the nails have straightened, as shown in the photograph, though from loss of substance at the tips of the fingers these nails will always be shorter and more irregular than they would be normally.

The following report was kindly made for me by Dr. M. Call, adjunct professor of medicine in the Medical College of Virginia, and is the result of his examination of this patient Nov. 16 and 17, 1905:

"Extension of forearm good. Flexion of forearm excellent, with slight degree of pronation. With forearm extended, pronation and supination are good. Flexion and extension of wrist are both present, extension being the stronger, but both are of good force.

"Phalanges.—Flexion of little and ring fingers good, of middle finger less strong. Index finger has less strength than the middle, but all these fingers flex with considerable strength. All the phalanges flex except the first phalanx of the index finger, which has scarcely perceptible motion. Extension of all the phalanges occurs, that of the middle and index fingers being weaker than that of the little and ring.

"Thumb.—Slight flexion of terminal phalanx, less marked flexion in the first phalanx. Extension present in terminal phalanx, less marked in first phalanx. Abduction and adduction both present to slight extent. Very little backward movement. Rotation can not be accomplished. With the hand at rest the thumb is slightly adducted.

"Nerves.—Galvanic stimulation of nerves gives the following result: Ulnar, below the point of implantation, gives marked contraction. Stimulation of the median gives marked contraction, but weaker than results from stimulation of the ulnar, especially weak in the thumb muscles supplied by the median. Musculo-spiral could not be located at the radial point, though the corresponding nerve on the uninjured side showed marked contraction. Stimulation of area just over the region of posterior interosseous nerve gives marked response in muscles supplied by that nerve, though the contraction of some of these muscles was due to unavoidable direct stimulation of the muscles themselves.

"Stimulation of the ulnar nerve above the implantation of the median gave ulnar and median response, the ulnar group being markedly stronger.

"No anesthesia or paresthesia. Partial cutaneous analgesia was marked on dorsal surface of middle finger and on plantar surfaces of index and middle fingers. There is marked atrophy in the muscles of right arm, forearm and hand, as compared with the well-developed muscular left side.

"The nails on the index and middle fingers show evidence of past trophic disturbances."

CONCLUDING REMARKS.

There are two features of this case that call for particular attention.

1. The first is an anomalous nerve supply to the extensors of the forearm. They were completely paralyzed at the time of operation, but, as the triceps was normal, the injury to the musculo-spiral must have been lower down in the arm, and it was thought unwise to attempt any operation on it till the median had been repaired. However, after repair of the median the extensors improved along with the flexors. The second operation showed the musculo-spiral degenerated to a marked degree, and, after complete section, motion of the extensors was not interfered with; so this improvement of the extensors could only be accounted for in two ways: (1) There may have been a high bifurcation of the musculo-spiral, the radial following the normal route of the musculo-spiral, the posterior interosseous, which may have been only temporarily injured, taking some other course. (2) The posterior interosseous may have been given off from, or at least have freely communicated with, the anterior interosseous of the median.

I stated the case by letter to Dr. George A. Piersol, professor of anatomy in the University of Pennsylvania, who replied as follows:

"By your first operation we may assume that the median was regenerated. Now in some reported cases the anterior in-

terosseous of the median had communications with the posterior interosseous of the musculo-spiral. Supposing that such paths were present, might not their existence have guided an unusual number of regenerating fibers to the extensors under the stress of needed additional supply, since the usual source (the musculo-spiral) was defective?

Dr. C. M. Miller, professor of anatomy in the Medical College of Virginia, agrees fully with Dr. Piersol in this solution of the case.

2. The second point of special interest is the trophic disturbance on the backs and tips of the index and the middle fingers. It is claimed by many anatomists that the tip of the index finger and the back of its last phalanx, together with the tip and back of the last and a portion of the second phalanx of the middle finger, are supplied by the median and not by the radial; though even these anatomists admit that there is free communication between the radial and median in this region. It must also be recalled that the root of the nail extends half way between its apparent base and the last phalanx-joint. Trophic disturbances in this area would unquestionably affect the nail profoundly, and the supply of the radial could very readily reach this region from a normally distributed nerve. But, in this case, with such an evidently anomalous nerve supply of the forearm and hand, it is likely that the radial went as far as the tip of the index and middle fingers. The fact that the posterior interosseous probably derived most of its nerve fibers from the median would tend to show that practically all of the fibers from the musculo-spiral went into the radial nerve, which would then be larger than usual, and consequently would be likely to be more widely distributed than is usually the case. The branches of the ulnar can easily account for the undisturbed condition of the ring finger and those of the musculo-cutaneous for the healthy appearance of the thumb. If the trophic disturbance of the index and middle fingers had been due to the median nerve, the thumb would have been affected. Mr. Hilton, in his classical work,¹² records the case of a sailor in whom the pressure of callus on the median nerve produced ulceration of the index and middle fingers and of the thumb. All of the ulcers healed promptly when pressure on the median was relieved. As has been mentioned above, complete mechanical destruction of a nerve unaccompanied by irritating conditions should not produce any trophic disturbance beyond simply atrophy. Such was the case with the median nerve. The radial, on the contrary, had undergone marked degeneration and the musculo-spiral had evidently received sufficient injury to cause total suspension of the function of the radial for some months, with the probability that without implantation its function would never have been satisfactorily restored. The lesion was probably of such a character that after several months just enough of its function returned to promote the trophic changes mentioned. That the radial nerve at the time of the second operation was incapable of conducting impulses to any marked degree was shown by the absence of appreciable change in the area of anesthesia over the backs of the index and middle fingers following the section of the musculo-spiral nerve. The disappearance of the trophic symptoms a few months after the musculo-spiral was implanted into the median also tends to show that they were due to the radial nerve.

DRUG ADDICTIONS.

PRELIMINARY REPORT OF THE COMMITTEE IN SECTION ON NERVOUS AND MENTAL DISEASES.²

SMITH ELY JELIFFE, M.D., Ph.D.
Chairman of the Committee.

NEW YORK.

At the last regular meeting of this Section of the American Medical Association a discussion was held on the subject of drug addictions, one of the results of which was the appointment of a committee to formulate some plan for the outlining of a system of procedure which would lead to some definite knowledge of the subject. Accordingly a committee was named of Drs. Smith Ely Jeliffe, New York, chairman; Brooks E. Beebe, Cincinnati, and Albert E. Sterne, Indianapolis. Inasmuch as the different members of this committee are distributed pretty widely over the United States, it has been impossible for them to get together. Therefore, the following syllabus of the report should be considered more as a report of progress from your chairman than as a complete report of the committee as a whole.

The committee feels that the scope implied by the words "drug addictions" is too extensive for consideration at this time, inasmuch as it would include the enormous subject embraced by the modern study of alcohol, opium, hashish, coca and other drugs, all of which are widely used to the detriment of the individual and social body. They have, therefore, thought best to limit their labors for the present to the subject of opium.

Inasmuch as the matter of terminology was brought up at the last meeting, we felt that our ideas on the subject might not come amiss. Almost an hour was devoted to the discussion of just what term should be used, and your committee feels that such time is spent to little advantage. It matters little whether one speaks of the opium habit, the opium disease or the opium addiction.

Your committee feels that the only service it can render to this Section at this time is to formulate, if possible, a series of suggestions concerning lines of fruitful inquiry. There are a large number of problems that must be solved, so great a number, indeed, that it would be futile at this time to suggest them all. We have, therefore, limited ourselves to some that seem to us most prominent at the present time, and as such they are offered to this Section, in the hope that some of the members who may hear or read this report may do some work through the year along the lines indicated and give the results of the inquiry at the next session.

1. The first problem concerns the *distribution and spread* of the habit. It is well known to many how universal the use of opium is in some of its various forms. Many of us are conversant with the fact that in small rural communities enormous numbers of the population are addicted to the use of the drug. Were it not for the enormous sale of official preparations of opium many drug stores would hardly exist. Therefore, it becomes important to determine more accurately just how widespread this practice is. At the present time we have no competent method outlined by which we may arrive at the information desired. Grinnell's studies in Vermont were, perhaps, most far-reaching and satisfactory, but these are open to many misinterpretations. Still we feel that perhaps the best way of getting at this matter would be through the pharmacists of a state or community. Also it might be suggested that prison statistics might be of service. There are many numbers here who are attending physicians to some of the large state institutions where an enormous number of opium habitués are known to be confined, for opium taking among the criminal classes is known to be almost universal.

A member of your committee has had under consideration for some time a study of the cures advertised in the daily press, and we feel that this also offers a suggestion whereby information as to this matter of frequency might be obtained.

² Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

2. The second problem concerns rather the proportionate number of individuals who take the drug by mouth, by hypodermic use, or by other methods, as smoking, etc.

3. The third problem is concerned with *etiology*. In other words, what are the origins of the habit, what induces people to take it up? It is well known that pain is an extensively potent cause. If so, what is the proportion of those that are induced to take up the habit by continued pain, and how may that be avoided by more carefully impressing on the medical fraternity the dangers of the use of opium as an analgesic? What is the influence of environment on the development of this habit. We have already spoken of the criminal class as particularly prone to this addiction. What are the factors which render it easy of access to this closely knit community?

4. From the individual etiology apart from the social, the psychologic study of *euphoria* might be taken up to advantage. Notwithstanding the classical controversy of De Quincey and Coleridge, we are far from the modern conception of the elements that constitute the euphoria of opium, and close analysis of the psychic mechanism under the influence of this drug from the standpoint of modern psychologic methods is very much needed.

5. The *pharmacology* of opium is in need of further investigation. The molecular formulas for morphin and its related bodies are in need of more definite analysis, that we may know just what base is responsible for the activities of the drug. The modifications known to exist in the activities of methylmorphin, dimethylmorphin, etc., offer the suggestion that the chemical study is not without its possible revelations.

6. Naturally the topic that interests us most concerns itself with the *treatment*. This should be considered from the *social* point of view as well as that of the *individual*, for in the very factor for which environment is responsible for the spread of the habit, legal or other regulations may be satisfactorily brought out that might reduce in part this important etiologic factor. Your committee does not anticipate in this study of social prophylaxis a topic that they believe can be handled by any one worker, for in its unraveling one must go to the very main springs of human corruption. Graft, protection money, debauchery, are the faggots that boil the pot of this modern wilest brew.

From the personal therapy side, however, your committee feels that the study of the *abstinence symptoms* is of intense importance. Concerning them there seems to be more misinformation than definite information in our standard text-books. The cause of the abstinence symptoms must be capable of understanding from the point of view of abnormal physiology, and this study can certainly afford very fruitful results. Closely bound up with the phenomenon of *tolerance*, of which everyone who has seen these patients is fully aware, is that of the possibility of the question of immunity. Are there antibodies formed which permit of this tolerance to the drug which is so well known, or does the body take on increased excretive powers, permitting it to break up more alkaloids with this increased use?

These two topics, both carefully studied by Faust and left undetermined, are probably capable of solution, and your committee offers them as some of the matter fruitful for the future.

Trusting that the report herewith submitted may be of some service, in the sense that some of the members of the Section may be led to engage themselves in the investigation of some of the topics suggested, your committee rests with thanks.

64 West Fifty-sixth Street.

ACUTE ARTICULAR RHEUMATISM.*

C. W. HARGENS, M.D.

HOT SPRINGS, S. D.

This paper does not assume the pretension of being a complete discussion of this disease, and only a few of the most important points in the general discussion, diagnosis, differential diagnosis, etiology and treatment, are discussed. The statements here made are the result of a large clinical experience extending over a period of fourteen years' residence at Hot Springs, S. D., and in treating cases of acute articular rheumatism with the assistance of modern hydropathic procedure, latterly in an institution thoroughly under control, employing an alkaline thermal mineral water, and aided by climatologic and topographic conditions, embracing an altitude of 3,400 feet, an excessively dry, sunshiny climate, free from great sudden atmospheric change, some of which factors possibly operate in giving me an experience and ideas different from that of practitioners not so located.

Acute articular rheumatism is an acute febrile affection, non-contagious, characterized by a nomadic multiple arthritis, profuse sweating and prone to endocardial complications.

The term "rheumatism" is an omnibus into which many practitioners dump all ill-defined pains, conditions and states troublesome and not well understood, a sort of refuse heap to which the salicylates are applied without beneficial results, and whereof the treatment of acute articular rheumatism and rheumatism in general falls into desrepute. Even that classical difficulty, acute arthritis deformans, seldom recognized as such, is almost always diagnosed as acute articular rheumatism and treated as rheumatism, not only without influence on the progress of the disease, but with detriment to the patient. Out of the many cases of arthritic deformans that I have seen I have never been able to elicit from the patient the statement that his case was diagnosed as such in its acute stages, but he has uniformly stated that his attending physician had pronounced it rheumatism. Also, I find that his physician continues to diagnose as chronic rheumatism nearly all cases of chronic arthritis deformans. For me to delve into the many arthritic conditions to which the term rheumatism is erroneously applied is beyond the scope of this paper. Acute articular rheumatism may be speedily recovered from and almost never becomes chronic. These so-called cases of chronic rheumatism are seldom true rheumatic arthritis, but are usually gout, arthritis deformans, articular disturbances due to pathologic states of the nervous system or to some form of coccus infection.

I wish to eliminate from the discussion all non-articular affections and all multiple articular affections, distinctly due to the various forms of coccus infections, and to make a plea for the elimination of the term "rheumatism" as coupled with that of a specific coccus infection. The elimination of such terms as "rheumatoid arthritis" and "gonorrheal rheumatism" will be a long step along the line of proper diagnosis and treatment. There is as much sense in pronouncing a case of tubercular rheumatism of the hip joint as in pronouncing a case gonorrheal rheumatism of the knee joint. The idea that heat, pain, swelling, tenderness, redness and stiffness in or about a joint is necessarily rheumatism or rheumatic is responsible for many sins of omission and commission.

* Read before the South Dakota State Medical Society at Deadwood, 1905.

Encouragement One-third the Business of the Physician.—Dr. Richard C. Cabot of Boston, in describing the impotency of the physician to affect through his technical skill or knowledge much that he would like to do, said: "Encouragement is one-third the business of the physician, but if it is to be permanent and not a mental cocktail, we must give the patient good reason for being encouraged, which usually means rejection of its equivalent. It is the disregard of these facts that has sent so many patients away from physicians and into the hands of Christian scientists and mental healers."

I have never seen a case of non-articular arthritis that I could safely pronounce rheumatism.

Acute articular rheumatism has the characteristic of being a multiple arthritis and of anubulating from joint to joint, with improvement in the joints previously involved. This is not true of coccus infections and of arthritic conditions due to pathologic states of the nervous system, to which the latter class, arthritic deformans, probably belongs.

Whenever you have a case where one, two or three joints are involved, and these joints only, and persistently so, you have not a case of acute articular rheumatism. The scope of this paper does not admit of going into a detailed account of the differential diagnosis between acute articular rheumatism and other articular affections. However, acute arthritis deformans is so often confounded with rheumatism that I will mention a few of the cardinal points of difference.

The onset in both diseases is sudden and similar. After a day or two in acute arthritis deformans there will be a temperature not high and not in proportion to the amount of arthritis present; that the joints are swollen, but not red and not so hot; that in arthritis deformans the swelling is more in the peri-articular structures; that the pain is less severe and that the joints can be moved without that excruciating pain found in acute articular rheumatism; that the patient can bear the weight of the bed clothes; that while polyarthritis is present in both diseases in acute arthritis deformans it is not shifting; that the joints involved are persistently involved; that the arthritis, if involving the fingers, gives a fusiform shape to the joints; that the cervical and maxillary joints are often involved; that there is not the tendency to endocardial complications; that salicylates do not influence the progress of the case, and that the case tends to become chronic and later to develop all the pathologic states characteristic of chronic arthritis deformans.

As to the etiology of acute articular rheumatism, that at the present time is a much debated question. Is or is it not a specific microbic infection, or is it microbic and not specific? Dr. McCrae, of Johns Hopkins, in an analysis of 270 cases of acute articular rheumatism, states that the cultural results were "practically negative," not only that, but of "negative value especially in reference to the absence of streptococci and staphylococci from the cultures." Recently the bacterial phase of the etiology has been summed up in an editorial in the Feb. 4, 1905, number of THE JOURNAL of the American Medical Association as follows: "Cole, of Baltimore, and Jachmann, of Breslau, among others, have failed to find the micrococcus of rheumatism or any other microbe in the blood or in the joints of typical cases of acute articular rheumatism." A fact which should excite suspicion in the mind of the student as to the bacterial etiology is that the varieties of microbes claimed to be isolated and specific are about as numerous as the claimants, and the fact that the various forms of micrococci will produce arthritis and endocarditis.

Clinical experience has demonstrated to me the marked difference in which cases of acute rheumatism yield to the treatment subsequently to be outlined, and has suggested the possibility of the dissimilarity of the operating cause or causes in two apparently similar cases. The behavior of the majority of cases under treatment has suggested an autotoxic cause, as I have seen case after case that had run anywhere from a few days to six weeks, under what I term improper treatment,

make a recovery so rapid as to border on the marvelous; cases in which the rapid recovery apparently could be explained only on the hypothesis of limiting and preventing the formation of autotoxic causal agents and eliminating the products of abnormal metabolism; cases in which, if the causal agent is microbic, then sodium salicylate must be a specific, for we know of no microbe destroyed by starvation diet, or the withdrawal of certain classes of food, or by profuse elimination. On the other hand, I have seen cases, apparently typical but presenting various complications, among them cardiac involvement, angina or a history of angina, which, under the treatment, would improve up to a certain point and beyond which I failed to obtain the markedly rapid expected improvement, on the hypothesis of simply eliminating products of suboxidation; cases in which the treatment had to be modified and carried along lines based on the idea that I had a mild infection to deal with; cases in which sodium salicylate, on the basis of being a specific, influenced the case up to a certain point and there had to be employed cautiously or abandoned. It has seemed to me that children are most prone to cardiac involvement, and in a number of instances I have found them suffering from considerable cardiac disturbances following repeated attacks of angina, prior to the development of marked arthritic disturbances. There does not seem to be any doubt about the microbic agent in these cases. The remarkable effects of profuse elimination, of a rigid, limited, non-animal, non-vegetable alkaloid, non-toxin-forming diet is a weighty argument against the infectious origin of this disease, and one greatly in favor of the autointoxication theory.

Most of my patients suffering from acute articular rheumatism come from the active walks of life—growing children with lusty appetites to supply the needs of rapid growth, in whom we see digestive disturbances due to overeating and violent play; servants, laborers, freight conductors, cabmen, teamsters; individuals doing work that calls for active exertion, great physical energy; individuals subject to becoming overheated and then suddenly becoming chilled, individuals doing a work where in they are subject to exposure and sudden atmospheric changes—wet and cold. These conditions and factors seem to produce some variety of digestive disturbances leading to the formation of toxins in the alimentary canal, the absorption of these resulting in metabolic disturbances, and producing products of suboxidation and all the manifestations found in this disease, just as you have similar manifestations, only on a smaller scale, in gout. The relation between dietary indiscretion, digestive disturbances and the operation of resulting autotoxic agents in gout are facts beyond cavil; why not acute articular rheumatism, both are arthritic, the one involves a few joints, the other many, with numerous similar manifestations, differing in degree only, and both amenable to somewhat similar lines of procedure?

Now the weakened and altered state of the tissues as the result of the operation of the toxic agents and disturbed tissue metabolism leads to a reduction of the vital resistance and your patient is subject to secondary microbic invasion. This, I hold, is what occurs in many of the cases and we have as a result infection complicating the results of autointoxication, with resulting cardiac involvement. These are the cases to which the treatment subsequently to be outlined is applicable in part only and must be modified to cover the infective element. In view of these clinical observations, I have come to make the statement that acute articular rheuma-

tism is a disease that is first, and in the great majority of cases, autotoxic, and that the autotoxic agent is probably some form of suboxidation due to toxic invasion from the alimentary canal, just as gout is produced by toxic invasion from the alimentary canal; secondly, that acute articular rheumatism is often complicated by microbial invasion, but that the infection is secondary to the conditions wrought by the disturbed metabolism and made possible by them. Recognizing this theory, early proper treatment will promptly relieve the case and in almost all cases the secondary infection can be prevented, and thus the more dangerous complications be prevented or greatly modified.

TREATMENT.

There can be no jugglery in the treatment of this disease; the least digression from a few of the points mentioned means disaster; skepticism as to the existence of a successful treatment of acute articular rheumatism and the prevention of its complications is based on errors of diagnosis. By eliminating these errors of diagnosis and rigidly carrying out the treatment indicated, one will be eminently successful. Cases complicated by cardiac involvement are cases complicated by infection and one must recognize this element in treatment. I realize that in the treatment on which I insist there is one element very difficult to obtain, especially for those engaged in country practice. I refer to the bath tub. Without the tub there will be more or less failure. To a certain extent this can be overcome by some improvised hot-air apparatus.

I have been profoundly impressed by the importance of two elements in the treatment—first, the prime necessity of limiting the quantity of food taken and the withdrawal of all proteid or xanthin-forming foods, and, secondly, with the prime importance of the care of the skin and profuse elimination from all the excretories.

First.—Place the patient in bed between dry woollen blankets, wearing a light night gown, with open sleeves fastened with safety pins. Keep the bed clothes dry at all times and never cold and clammy; give him absolute rest and plenty of dry, warm air in a sunshiny room.

Second.—Withdraw all food until the alimentary canal has been thoroughly emptied and cleansed; then for the first few days employ a strictly skim milk diet; then begin to allow stale bread and milk products. If milk is not well taken, cereal foods and buttermilk may be used. The carbonated waters often assist the difficulty in taking milk. Exclude all tea, coffee, cocoa and chocolate in the acute stages. When the patient has passed the acute stages he may gradually begin the use of fish, oysters, cottage cheese and the white meat of barnyard fowls, carefully returning to the proteid articles of diet and immediately abandoning them on a reappearance of the arthritic symptoms. Easily digested green vegetables, such as new peas, string beans, lettuce, asparagus, spinach and a small quantity of baked and mashed potatoes are allowed. Exclude all acid and sweet fruits. Oranges are freely allowed. It will be well to keep watch of excessive amounts of starchy foods and heavy sweets.

Third.—Give a vigorous dose of calomel, follow this with epsom or rochelle salts, and thereafter keep the bowels moving from two to four times each twenty-four hours with the salts or some other agreeable form of saline laxative. I am partial to the magnesium sulphate.

Fourth.—Give tub baths. Place the patient in water at 98 degrees; after he has been in the tub five min-

utes, add hot water gradually to bring the temperature to 100 or 102 degrees. Keep patient in the bath fifteen to twenty-five minutes, as he will bear, guarding against sensation of faintness or marked depression. Give patient skin friction, massage and passive movements entire time he is in the bath, in the order named. In removing patient from the bath be careful not to expose the skin to the air, quickly throw a dry, warm sheet and blanket around him, and get him into bed between dry, warm blankets. Now pack hot bottles about him and gradually bring on free perspiration, keeping this up from three-quarters to an hour and a half.

Fifth.—Now begin to give ten to fifteen grains of sodium salicylate with a glass of alkaline mineral water every two hours. Half a glass of milk may be given with a little seltzer water in place of the full glass of water if sodium salicylate causes great gastric disturbances. I seldom employ more than two drams of sodium salicylate in the twenty-four hours, and deem that dose sufficient for almost all cases. Under the treatment so far outlined one will be surprised at the size of the dose of sodium salicylate one can give without getting the customary toxic effects and gastric disturbances. Experience proves that patients taking hot baths with free elimination can take large doses of depressing drugs without the usual toxic effects, and it is very seldom that I am compelled to modify my dose of sodium salicylate. Now, as soon as the patient improves and gets comfortable, try to lengthen the interval between doses and continue the work along the line of reduction.

Sixth.—Flood the system by the internal administration of large quantities of an alkaline mineral water, giving it to him at regular stated intervals. If mineral water is not at hand, employ pure water, holding sodium bicarbonate or potassium citrate in solution. Keep the urine alkaline or neutral by the administration of alkaline mineral water.

Seventh.—Locally apply hot fomentations to the affected joints, or wrap in cotton batting or wool and apply a splint.

Eighth.—Unless the weather is warm, dry and free from sudden changes, keep the patient in bed for at least a week after the temperature has become normal. Caution him against exposure. It is astonishing how little exposure will bring on another attack within a week or ten days following an apparent recovery.

Now, this is an incomplete discussion of this disease and the scope of this paper does not admit of going into all the details and of discussing the changes in diet, treatment, etc., in the subacute and possibly chronic stages. Before closing, however, let me add the caution to get rid of the salicylate as soon as possible and to substitute the syrup of iodid of iron and Fowler's solution, as these patients become very weak and often markedly anemic. Also, one should not adhere forever to the non-proteid diet. The patient will do badly, recover slowly and poorly; so go back to a mixed and proteid diet as soon as possible, watching for a possible recurrence of the arthritic symptoms.

Peritoneal Adhesions.—Lejars calls renewed attention to those not infrequent cases where gastrointestinal symptoms followed some time after an apparently slight injury to the abdomen. These symptoms include rebellious colics, vomiting, constipation or diarrhea, without other evidences of organic disease. When the presence of adhesions simulates ulcer, gallstones, etc., operation with loosening of the adhesions is indicated. *Denver Medical Times.*

SPINAL ANESTHESIA BY MAGNESIUM SULPHATE.

A REPORT OF SEVEN OPERATIONS PERFORMED UNDER ITS INFLUENCE.

H. A. HAUBOLD, M.D.
Attending Surgeon, Harlem Hospital.

AND
S. J. MELTZER, M.D.
Consulting Physician, Harlem Hospital.
NEW YORK.

EXPERIMENTS ON ANIMALS.

In several series of experiments on animals¹ it was established that magnesium salts have very distinct anesthetic properties. Among other things it was established that by local application of solutions of magnesium sulphate on nerve trunks the conductivity and excitability of motor and sensory nerves can be temporarily abolished; that by subcutaneous injection of certain quantities of magnesium salts general anesthesia with complete recovery could be produced in several species of animals, and, finally, that by intraspinal injections into animals of comparatively small doses of a solution of magnesium sulphate a complete anesthesia and paralysis of the posterior part of these animals could be produced.

These latter experiments interest us here particularly and we shall dwell on them a little longer. The experiments on dogs, cats and rabbits have demonstrated that by application of solutions of magnesium sulphate to the spinal cord, either through an opening made by laminectomy or through lumbar puncture, the sensibility and motor power of the posterior extremities became greatly impaired or were even completely abolished. The experiments on these animals, however, were not entirely satisfactory. In lumbar puncture in these animals the cord was sometimes unavoidably injured, which marred the results, and the injections through a laminectomy opening had the disadvantage that a part of the solution escaped again through the opening and that the quantities used could, therefore, not be measured exactly.

In monkeys, however, lumbar puncture can be carried out nearly with the same degree of safety and reliability as in human beings, and the experiments have here given uniform results. The injection of a solution of magnesium sulphate in a dose equal to about 0.06 (one grain) of the substance to one kilogram weight of the animal would cause, within a few minutes, complete paralysis, and anesthesia and paralysis would spread upward, reaching neck and head, and the animals would then lie in a state of stupor and paresis. The monkey, which an hour before was fighting and biting every one who came near him, would lie now perfectly limp, offering not the slightest resistance. The vital reflexes were not affected, heart beats were not changed; only the respirations were slightly slowed. The animal would remain in that state for many hours, but on the following morning would be found completely recovered. A few animals stood several consecutive injections at comparatively short intervals apparently without any after-effect. A dose four times as large as the one above mentioned proved fatal to the animal.

From the experiments with intravenous injections the observation should be mentioned here that solutions of

magnesium sulphate are very toxic, even in small doses, especially when injected at a rapid rate. The toxic effects, however, are essentially confined to the function of respiration; heart and blood pressure, if the dose employed was not too large, remain practically unaffected. In animal experimentation, therefore, an intoxication with magnesium salts does not necessarily lead to a fatal issue; on the contrary, the most stubborn respiratory paralysis has been successfully overcome by patiently and perseveringly carrying out proper artificial respiration, i. e., insufflations of air into the trachea by the methods commonly employed in physiologic laboratories.

SPINAL ANESTHESIA IN HUMAN SURGERY.

The question now arose: Could intraspinal injection be employed in human surgery? Spinal anesthesia seems to be now a well-established method. Its history is of very recent date. It began with the lumbar injection of cocaine.² Influenced apparently by the International Medical Congress in Paris (1900) and by the enthusiasm displayed by Tuffier for the method and the drug, spinal cocainization soon began to be employed abroad and in this country extensively. This widespread activity, however, was soon followed by a reaction against the method. Bier himself was one of the first to warn against its indiscriminate use. Cocain proved to be poisonous even in very small doses. (It is a noteworthy fact that spinal cocainization was not tested in experiments on animals before its employment in human surgery.) Eucain did not give better results.

Recently, however, the pendulum began again to swing in favor of spinal anesthesia. Stimulated by the observations of H. Braun on local anesthesia, Bier and others found that the addition of suprarenal extract makes cocain more available also for spinal anesthesia. Furthermore, in stovain, a new synthetic product of the cocain group, a drug was introduced which is somewhat less effective, but it seems to be also less poisonous than cocain. Judging from the number of favorable reports which we now find in the surgical literature on long series of operations carried out under spinal anesthesia by one or the other method, the conclusion seems to be justified that spinal anesthesia as a method has now come to stay.

USE OF MAGNESIUM SALTS.

Could magnesium salts also be employed by this method in human surgery? We felt convinced that an attempt to test it was thoroughly justified for the following reasons: As stated above, in animals standing nearest the human species, in monkeys, spinal anesthesia by magnesium salts has given complete satisfaction; there was complete anesthesia of the posterior part of the animal, which was followed by complete recovery, and the experiments have shown that even repeated anesthetization of the animal by this method left no after-effects. Also, the dose which was amply sufficient to produce complete anesthesia was only about one-fourth of the fatal dose—a latitude between the anesthetic and the fatal dose much greater than in most of the other anesthetics. Moreover, the danger which might come from the administration of magnesium salts was not through failure of heart or blood pressure, but only through impairment of the respiratory function, a danger which is amenable to relief by artificial respiration efficiently carried out. The fact that magnesium is not

1. The experiments were carried out at the Rockefeller Institute for Medical Research by Drs. S. J. Meltzer and John Amer; Amer, *Jour. of Physiol.*, vols. xiv and xv; also *Amer. Medicine*, Nov. 25, 1905. And S. J. Meltzer: *Medical Record*, Dec. 16, 1905.

2. L. Corning, 1894; A. Bier, 1898.

an alkaloid or an artificial synthetic product like cocaine, etc., but a substance normally present in the body and an integral part of its living tissues does certainly not speak against its employment as an anesthetic.

It should also be stated that, differing from cocaine, magnesium salts can be thoroughly sterilized by heat without affecting in the slightest their anesthetizing property. Finally, it should be remembered that, differing from the interests in favor of the employment of patented synthetic products, like stovain, alypin, etc., the attempt to employ magnesium salts in human ills was dictated by no other interest than desire to increase our store of knowledge and to benefit humanity.

Being thoroughly convinced of the justification of our undertaking, seven operations under the influence of spinal anesthesia by magnesium sulphate were performed in the Harlem Hospital during the surgical service of one of us (Haubold). In order to reduce any possible danger still more, it was decided to employ in human surgery, at least at first, a dose equal only to about one-third of that which proved to be harmless and efficient in animals, i. e., to inject by lumbar puncture a quantity of a solution of magnesium sulphate which would contain about 0.02 (1/3 gr.) to about one kilogram (about 2 pounds) body weight. Not expecting a complete anesthesia from such a small dose, we were ready to assist the effect by some degree of general anesthesia.

CASE REPORTS.

Herewith we give a brief account of the results:

CASE 1.—Mrs. M. M., aged 25, Sept. 4, 1905.

Operation.—Perineorrhaphy, including sphincter, and curettage.

At 3:15 p. m. a lumbar puncture was made and about 5 c. c. of spinal fluid permitted to escape. Five cubic centimeters of a sterile 25 per cent. solution of magnesium sulphate (equal to about 1 c. c. of the solution to 25 pounds of body weight) were injected. One hour later anesthesia of perineum was marked but insufficient. Chloroform was administered and operation was begun at 4:20 p. m. Operation was finished at 5 p. m. Only about 10 c. c. of chloroform were used; the anesthesia was complete. At the conclusion of the operation the condition of the patient was good.

No note of condition of patient was taken between 5 and 7 p. m. At 7 p. m. patient was completely unconscious and could not be aroused. There were no reflexes. Patient remained in this condition until 9 p. m., when she could be slightly aroused. There was no reaction to pain in lower half of the body. Incontinence of urine and feces. Temp. 99, pulse 80, resp. 18.

For the greater part of the night she remained in a semi-comatose state. At 3:30 a. m. she flexed knees, and from 5 a. m. to 7:30 a. m. vomited small quantities four times. At 9 a. m. she was still drowsy, could move her legs, felt pain but could not localize properly. She had to be catheterized. Temp. 101.6, pulse 101, resp. 22.

Temperature and pulse returned to normal next day. Retention of urine, incontinence of feces and other symptoms disappeared in 24 hours. The patient then made an uninterrupted recovery and was discharged as completely cured on September 21. (Patient returned to the hospital on January 11 with an attack of appendicitis. She had no after-effects whatsoever from the intraspinal injection.)

CASE 2.—Mrs. R. S., September 27.

Operation.—Curettage for metrorrhagia.

At 3 p. m. a lumbar puncture was made; about 5 c. c. of spinal fluid were removed and 5 c. c. of a 25 per cent. solution of magnesium sulphate were injected. After 6 minutes there was a profuse perspiration and patient was restless. After 12 minutes there was motor paralysis from the pelvis down; sensation was diminished, but insufficient for operation. At 3:25 chloroform was administered. The operation lasted 20 min-

utes. Five cubic centimeters of chloroform were used, and there was absolute relaxation of all muscles below waist line. Patient was unconscious, but conjunctival reflex was present.

At 4:15 p. m. patient was partially conscious and moved arms; lower extremities were paralyzed. At 6 p. m. patient was in profound narcosis; all reflexes were lost; there was faint response on tickling mucous membrane of the nose. At 2 a. m., September 28, patient talked incoherently; was still semi-comatose. At 6 p. m. sensation returned in lower extremities. Motion did not return until 4 p. m., when for the first time also her speech became rational. From 11 p. m., September 27, to 5 p. m., September 28, patient vomited nearly every hour, this vomiting being only regurgitation, as the abdominal muscles were not used. At 1 p. m., September 28, patient's temperature rose abruptly to 105°, pulse was rapid, but respirations remained normal. Temperature gradually came down and in two days became normal. (The fever was apparently due to an intrauterine infection.) Retention of urine lasted about 36 hours. On October 1 patient felt well in every respect. There were no after-effects. After one week the patient was discharged, cured.

Remarks.—In both cases the amount of chloroform used was too little to have a prolonged after-effect. In both cases the deep general anesthesia did not set in until some time after the operation; in the second case the patient was out of the mild general anesthesia soon after the operation. The late deep general narcosis was apparently due to the magnesium sulphate alone, or to the magnesium sulphate plus the small amount of chloroform.

CASE 3.—Mrs. P. T., aged 22, September 29.

Operation.—Dilatation of cervix.

At 3:10 p. m. 5 c. c. of 25 per cent. solution of magnesium sulphate were injected by lumbar puncture. The weight of patient was over 150 pounds, hence the solution of magnesium sulphate was less than 1 c. c. to 30 pounds. There was profuse perspiration after 7 minutes. After 40 minutes there was no loss of sensation and no paralysis. Chloroform was administered and the operation performed. About 4 c. c. of chloroform were used; there was no general anesthesia, but no pain was felt and no resistance was offered during operation.

No impairment of consciousness followed; there was no vomiting and no retention of urine. Sensation in legs remained distinctly impaired until 10 p. m. On September 30, at 1 p. m., temperature began to rise and by noon reached 103°; pulse went up only to 85. Next day temperature became normal again. Patient felt well and was discharged October 2.

Remarks.—In this case the dose of magnesium salt was too small. It was, however, in conjunction with the small dose of chloroform, apparently sufficient to permit the performance of the small operation of dilatation of the cervix.

CASE 4.—Mrs. M. McD., aged 27, October 21.

Operation.—Laparotomy for removal of appendix and right ovary and tube.

At 1 p. m. a lumbar puncture was made, about 4 c. c. of spinal fluid withdrawn and a little over 4 c. c. of a 25 per cent. solution of magnesium sulphate injected. Patient's weight was about 110 pounds—a little over 1 c. c. of the solution to 20 pounds body weight. At 4:30 p. m. there was paresis, loss of reflexes and anesthesia from the pelvis downward. Patient was moaning; pulse 94 and good. Chloroform was administered, patient was under in a few minutes and operation was begun. Patient was sometimes out of anesthesia, but a few drops of the chloroform sufficed to put her under again completely. Anesthesia was ideal; there was not the slightest resistance. Pulse 70, good quality; resp. 26. When out of anesthesia patient apparently did not feel surgical manipulations. At 4:55 p. m. operation was finished and chloroform discontinued. Sixteen cubic centimeters of chloroform were used, greatly wasted.

At 5 p. m. spinal puncture was made again, 4 c. c. of spinal fluid being withdrawn and 5 c. c. of sterile normal saline injected. This procedure was repeated three times; the last time 8 c. c. of sterile normal saline were injected into the spinal canal. Patient was in good condition. Pulse 60, respiration 26.

At 6 p. m. patient was awake, somewhat confused. At 7

p. m. mental condition was normal and sensation in lower extremities had reappeared. Pulse 70, resp. 24. Motor power returned about 9 p. m. In the course of the night there was a slight rise of temperature. On October 22 at 9 a. m. temperature was highest, 100.6, pulse 100, resp. 24. The temperature, etc., became normal in the course of the day. She vomited once, slightly, about 2 p. m. Otherwise the general condition was good. She made a rapid recovery and was discharged, cured, November 6. She was seen in January, 1906, and had had no after-effects whatsoever.

Remarks.—Although the operation in this case was more serious and extensive than in the first two cases, and although more chloroform was used, there were practically no after-effects at all. The favorable result can reasonably be ascribed to the postoperative washing of the spinal canal which was practiced in this case.

CASE 5.—C. H. B., aged 57, October 27. Alcoholic, with marked arteriosclerosis.

Operation.—Correction of malunion of Pott's fracture of right leg.

At 1:15 p. m. lumbar puncture was made; 7 c.c. of spinal fluid were removed and 7 c.c. of a 25 per cent. solution of magnesium sulphate were injected. At 1:30 p. m. there was profuse perspiration. There being no distinct anesthesia or paralysis, at 3:45 p. m. chloroform was administered and the operation was finished at 4 p. m. Sixteen cubic centimeters of chloroform were used, but the patient was not completely under its power. Pulse 60 and irregular.

At 4:30 p. m. patient was completely out of anesthesia and motion and sensation were present. His mind was in a state of confusion for about 24 hours. There was no vomiting. At 1 a. m., October 28, temperature began to rise and reached 103° by 1 p. m. It came down with fluctuations to normal by October 31. Patient was seen in the course of the winter and had had no after-effects from the spinal injection.

Remarks.—This patient's weight was about 160 pounds and he received a trifle more than 1 c.c. to 25 pounds body weight. There was some effect. For an alcoholic, 16 c.c. of chloroform are certainly insufficient to bring the patient into a state of complete anesthesia, and we may well assume that the intraspinal injection assisted greatly in keeping the patient in the required state of anesthesia. But, comparing it with the other cases, the effect must be considered as slight.

CASE 6.—Mrs. S. R., aged 27, October 31.

Operation.—Bassini for relief of femoral hernia.

At 2 p. m. spinal puncture was made. 7.5 c.c. of spinal fluid were removed; 7.5 c.c. of 25 per cent. magnesium sulphate were injected. At 4 p. m. there was no sensation of pain in legs, but tactile sensation was present. Motor power was distinctly diminished, but reflexes were present. Chloroform was administered and operation begun. At 4:15 p. m. operation was finished and chloroform was discontinued. The amount of chloroform used was only 8 c.c.

Patient was never completely under. She felt that she was handled around the lower part of the abdomen, but felt no pain and offered no resistance. At 5:30 p. m. pulse 60, resp. 20. Complete motor paralysis of extremities, very little sensation of pain, but tactile sense present in a measure. Mental state somewhat confused. One hour later patient was perfectly rational and sensation had returned. Motor power returned about 10 p. m. and reflexes about 6 o'clock next morning. Patient vomited four times.

At 1 a. m., November 1, temperature began to rise and reached 101° at 9 a. m., and it then gradually declined and became normal on November 2. She was discharged, cured, November 14. She was seen January, 1906. She had no after-effects.

Remarks.—The spinal injection of the magnesium sulphate in this case was undoubtedly the chief cause of the local anesthesia. The slight amount of chloroform used was only the means of diverting the attention of the highly hysterical patient. In this case the magnesium sulphate produced only analgesia; the tactile sense was only moderately impaired.

CASE 7.—A. A., aged 16, male, October 31.

Operation.—Operated for a large intramuscular abscess of right thigh.

At 2:30 p. m. spinal puncture was made; about 8 c.c. of spinal fluid were withdrawn and 8 c.c. of 25 per cent. solution of magnesium sulphate were injected. Patient's weight was about 120 pounds, hence he received 1 c.c. to 15 pounds body weight. At 2:50 p. m. his legs were heavy; no reflexes. At 3 p. m. motion was difficult; patient vomited. At 3:15 p. m. legs were paralyzed and anesthetic. Pulse 74, resp. 18. Operation was begun; no chloroform was given. Patient conversed and felt absolutely nothing of the operation. He vomited again a small amount of greenish fluid. At 3:50 operation was completed. Pulse 84, resp. 20. Returned to ward.

At 5 p. m. patient was in deep coma. There was complete muscular relaxation; all reflexes were absent except lid reflex. Pupils small. Pulse 70, good; resp. 11. At 6:15 p. m. pulse 72, resp. 10; other conditions were the same as before.

At 6:30 p. m. spinal puncture was made again, 4 c.c. of spinal fluid being withdrawn and 4 c.c. of normal sterile saline being injected. The same procedure was repeated three times more. At 7:10 p. m. the coma was not so deep; the patient resisted the opening of his eyes and groaned when disturbed. Pulse 72, resp. 15. At 8:15 p. m. pulse 80 and resp. 10 again, but he moved his head and answered questions, although very confusedly. At 9 p. m. pulse 88, resp. 22; pupils wider; patient opened his eyes again and answered questions better. At 10:30 p. m. mental condition improved; appeared to be resting comfortably; pulse 100, resp. 27; pupils still wider.

At 3 a. m., November 1, he was awake and rational; sensation in limbs had returned and he was able to move them; reflexes were absent. He complained of frontal headache and also of some pains in legs and feet. At 8 a. m. reflexes had returned. There had been no vomiting since the operation. At 1 a. m., November 1, temperature rose to 104° and remained so until 1 p. m. the same day. Pulse fluctuated between 116 and 124 and resp. between 24 and 30.

Temperature, etc., improved gradually and became normal on November 3. Patient had fever before the operation. On November 6 patient was transferred to City Hospital in good condition, where he recovered.

Remarks.—Three and a half hours after the spinal injection of magnesium sulphate this patient passed into a most complete state of general anesthesia without the aid of any other anesthetic. In that state any part of his body could have been operated on with the greatest ease. His leg was operated on under complete local anesthesia forty-five minutes after the injection. But this patient received the largest quantity of the solution: 1 c.c. to about 15 pounds body weight. Judging from our experience in the fourth case we have reason to believe that if the operation would have been followed immediately by "washing" of the spinal canal the patient might have been freed from the late general anesthesia. As it was, the late "washing" of the spinal canal shortened perceptibly the after-effects.

DISCUSSION AND CONCLUSIONS.

From the foregoing seven cases we may deduce a few conclusions.

1. Magnesium sulphate in intraspinal injection proved to be as efficient an anesthetic in human beings as it was found to be in animals. In Case 7 a certain dose of magnesium sulphate produced local anesthesia in 45 minutes after intraspinal injection and about 3 hours later a deep general anesthesia set in which lasted for many hours and which would have permitted any operation on any part of the body. Although the dose used in this case was the largest we have employed in human beings, it was still less than one-half of the dose we have regularly used with monkeys with perfect impunity. The experience in the first two cases, however, has demonstrated that even such a small dose as 1 c.c. of the 25 per cent. solution to 25 pounds body weight is capable of bringing out complete anesthesia and paralysis of the lower part of the body, although not until 2 or 3 hours after the injection. The anesthesia and paralysis observed in these cases, appearing about 2

hours after the operation, could certainly not have been due to anything else but to the magnesium salt. Even the general anesthesia which set in late in these cases was undoubtedly, in the main, due to the intraspinal injection, since the small amount of chloroform which was employed in these cases could never produce such an after-effect. In Case 4 the patient apparently could have been operated on even at that early hour without chloroform. The absence of any noteworthy after-effects in this case was surely due to the washing of the spinal canal. The washing of the canal, although carried out at a comparatively late hour, proved to be beneficial also in the seventh case; the respirations increased and all the after-effects were perceptibly shortened. In Case 4 as well as in Case 6 there was a stage of analgesia which permitted the operation, although the tactile sense was not abolished.

Case 3 has shown that a dose of 1 c.c. of the solution of magnesium sulphate to 30 pounds body weight is insufficient to carry out an operation by its aid alone, although it apparently supported, in a measure, the effect of the chloroform.

In Case 5 even a dose of 1 c.c. of the solution to 20 pounds body weight had only a moderate anesthetizing effect. This patient was an alcoholic, 57 years old, with markedly developed arteriosclerosis. Possibly alcoholism, as well as arteriosclerosis, interferes in some way with the anesthetizing effect of the magnesium salt. Possibly also there is an individual predisposition for or a resistance to the anesthetizing effect of magnesium. Our impression is that it affects younger individuals more readily than older ones.

2. It seems that the spinal injections caused a rise of temperature in all the cases. Although in the majority of the cases there were some other reasons for the appearance of fever, the setting in of the rise of temperature at about the same time and the similarity of the course of the fever in all cases made it probable that the intraspinal injection was essentially the cause. This is the more probable, since it was observed also in intraspinal injections of other substances. The course of the fever, however, was in all cases perfectly benign and disappeared after 36 or 48 hours. The pulse remained always of good quality.

Vomiting occurred in most of the cases. In Case 7, in which no chloroform was employed, vomiting occurred only twice and lightly, and only at an early stage. The frequent vomiting in Case 2 was probably not due to the intraspinal injections. It is noteworthy that in most of the cases the postoperative vomiting had only the character of regurgitation (no contraction of the abdominal muscles).

4. There was retention of urine, lasting between 24 to 48 hours, in nearly all the cases. The bowels also had to be assisted by enemata. The incontinence of feces of the first case was due to the involvement of the sphincter in the operation. We have to point out again that in Case 4, in which the spinal canal was washed immediately after the operation, there were practically no after-effects.

As far as seven cases permit any conclusions, the following statements may be made: Intraspinal injection of magnesium sulphate is capable of producing anesthesia, and, if carried out with caution, seems to be a safe anesthetic. The following plan would seem the best, at least for the present: To inject about 1 c.c. of a 25 per cent. solution of magnesium sulphate for every 18 or 20 pounds body weight and wait about 2 hours. It is

probable that by that time the analgesia will be sufficiently advanced to permit the performance of an operation on any part of the lower half of the body. A small dose of chloroform, however, should be administered to divert the patient's attention and to hasten and complete the anesthesia. Immediate washing of the spinal canal should follow the operation in all cases.

A more extensive experience will show whether this method could be used also as a means for general anesthesia for operations on the upper part of the body. It goes without saying that the solutions should be sterile, the salt chemically pure, and the patient handled with proper surgical care.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER X.

LOCAL DISINFECTANTS AND ANTISEPTICS.

Lister's use of local antiseptics in surgery is usually spoken of as a discovery, but, without detracting in any way from the credit due to Lister, it should be referred to more correctly as a practical application of previous discoveries.

Reichenbach, in 1832, obtained a substance from wood tar which he named *creosote*. Finding later that it consisted of phenol and phenol ethers, and also finding these same substances in smoke, he concluded, and later conclusively proved, that to them is due the meat preserving activity of smoke.

Runge, in 1834, found that the phenol which he obtained from coal tar also possessed the power of preventing putrefaction. Tar and a number of products of a similar nature were long ago recommended and widely used for foul smelling ulcers, but the fact remains that to Lister is universally, and very properly accorded the distinction of having placed antiseptic in surgery on a sure basis. Since the early days of antiseptic there have been many improvements, and we now know that the most perfect cleanliness, or asepsis, that is attainable is much to be preferred even to the most elaborate antiseptic.

It is, of course, entirely beyond the scope of this series of papers to consider the details of major surgery, but the principles of antiseptic which obtain in this branch are equally applicable to minor operations, and their disregard by many, who are not surgeons, is the best justification for their present brief consideration. The necessity of scrupulous cleanliness is seen in such a simple, but admittedly important, procedure as vaccination. The careful physician will perform even this comparatively simple operation under aseptic conditions, thereby saving himself much annoyance in case of accident.

The first, and really the most important, duty of the physician with regard to infections is to see that he does not carry them to other patients. There can be no doubt that physicians have played no small part in the spread of infectious diseases, particularly in the past, but fortunately, with the better understanding of the subject, this seldom occurs now.

The disinfection of clothing and of instruments belongs to the subject of general disinfection, that of the hands and person to local disinfection.

The cleansing of the hands, as it is done in a number of American hospitals, is about as follows: "Trim and clean the nails, wash the hands and forearms for five minutes in very warm, sterile water, using green soap and scrubbing them energetically with a brush or a gauze pad, cleansing the nails again during this part of the process. Rinse the hands for three minutes in 75 per cent. alcohol, to remove soap and to aid in sterilization; then in 1 to 1,000 solution of mercuric chlorid, or in a solution of 1 to 2,000 mercuric chlorid with 1 to 40 phenol, and finally rinse in sterile, warm water." This may be somewhat more elaborate than is necessary in most cases of minor surgery, but even here it is well to err on the safe side.

For the disinfection of the whole body a full bath in warm water with the liberal and judicious use of soap is sufficient, and the clothes may undergo disinfection separately at the same time. This procedure is so simple that the physician can not escape blame should he carry infection from one patient to another through the omission of necessary precautions.

When minor surgical operations are to be performed it is always well to thoroughly disinfect the surface at and around the prospective seat of operation. For this purpose the procedure given for cleansing the hands of the surgeon is sufficient, though in some cases it may be found necessary to supplement the soap and water with oil of turpentine.

Wounds and ulcers require disinfection to destroy those bacteria which can be reached, and antiseptic dressings to prevent the development of colonies from those which escape destruction or which may afterward reach the spot.

AQUA HYDROGENI DIOXIDI.—U. S.—Solution of Hydrogen Dioxide, or, as it is frequently called, Solution of Hydrogen Peroxid, is useful for decomposing pus, in which bacteria are protected from the action of other disinfectants. It thus secures the rapid cleansing of freely exposed pus cavities or ulcers, and at the same time it acts powerfully on bacteria, though they are not all destroyed so long as any pus remains. The official solution is equal, in disinfectant power, to a 1 to 1,000 solution of mercuric chloride. The action on pus of hydrogen dioxide is so extremely rapid that it frequently detaches small masses which may escape decomposition.

The use of this solution is not unattended with risks, particularly in sinuses or deep, partially closed wounds. Mucous membranes decompose hydrogen dioxide rapidly, and the skin slowly, with the liberation of nascent oxygen. It is not certain whether the bactericidal property is due to the liberation of oxygen alone, or whether the preparation possess a special influence on the micro-organisms. The decomposition whereby the oxygen is liberated is supposed to depend on a ferment, catalase, which is widely distributed, and, as the preparation loses its bactericidal powers, once the oxygen has been liberated, it is of course useless as an antiseptic, though extremely useful as a disinfectant. Hydrogen dioxide has an especial reputation in the treatment of sore throat and even diphtheria, for which it is used as a spray or as a gargle with entire safety. It attacks metals readily, and only rubber or glass should be used in connection with it. Diluted with an equal amount of water, it is an excellent mouth wash, but not infrequently contains a little acid, and the mouth should be rinsed after its use.¹

After the disinfection of ulcers and wounds an antiseptic dressing is applied. Cotton, gauze and lint impregnated with various antiseptics are found on the market. Only the active substances that are used in this connection will be discussed, as the application of dressings belongs to surgery.

IODOPORUM.—U. S.—Iodoform, Tri-iodomethane, is usually obtained by the action of iodine on alcohol, in the presence of an alkali or an alkaline carbonate. Iodoform was discovered by Séculas, in 1822, but was not used in medicine until some time after 1837. Despite its disagreeable penetrating odor, iodoform continues to hold first place among local antiseptics, used for the dressing of wounds. At first it was supposed to share with chloroform (from which it differs chemically only in the iodine displacing the chlorine) a strong antiseptic action, but, in the case of iodoform, this has been found to be but slight; it is, however, materially increased by the slow liberation of iodine. When its local use as a dressing is long continued, enough of it may be absorbed to produce poisoning, which does not, however, result in a typical narcosis, such as chloroform produces, but gives rise to disturbances of cerebration, headache, delirium and other symptoms. These are due to the iodoform molecule; but exanthemata, which are sometimes severe, are usually attributed to the liberated iodine, which, when liberated, is thought to circulate in the blood as an alkaline iodid or in combination with albumin. Hematuria,

albuminuria and urinary casts may also result from its absorption, and many attempts have been made to find a substitute for iodoform without its poisonous effects.

Some surgeons deny that iodoform exerts any direct antiseptic power, and attribute the benefits from its use to its limitation of the secretion on which the bacteria would otherwise develop. Binz observed that iodoform lessened the emigration of leucocytes, and it is said to be particularly useful in local affections with free secretions.

When iodoform is intended for use as a dusting powder, its odor may be rendered very much less disagreeable by incorporating with it 4 per cent. of coumarin. The following has been used to some extent:

R. Iodoformi	5v	20
Coumarin	gr. xv	1
Acidi borici q. s. ad	3xiii	50

Misce bene. Sig.: To be used as a dusting powder.

Pulvis Iodoformi Compositus (N. F.), containing Iodoform 20, boric acid 30, naphthalin 47, and oil of bergamot 3 parts, also constitutes a useful and comparatively unobjectionable antiseptic dusting powder.

Where iodoform is to be used in the form of an ointment the addition of from 5 to 10 per cent. of balsam of Peru, or of 2 per cent. of oil of anise has been found to be advantageous. The addition of oil of anise, in somewhat larger quantities, has also been recommended for iodoform gauze, particularly when the gauze is to be used in appreciable quantities or for any continued length of time. If the antiseptic action of iodoform is due to the liberated iodine, then necessarily many of the proposed substitutes must be practically devoid of antiseptic power, since the iodine is too firmly bound to be liberated by the tissues.

IODOL.—U. S.—Iodol designated chemically as tetra-iodopyrrol, one of the recent additions to the Pharmacopeia, illustrates this particular condition very well. The iodine in this case is so thoroughly combined that the substance has been recommended as being comparatively non-toxic. Another class of preparations, such as nosophen, isophan and europen, depends for the antiseptic action largely on the cresol or the phenol compounds united to the iodine. Loretin and vioform are combinations of iodine and quinoline, and there is no reason to suppose that they have any advantages over the other preparations just mentioned.

THYMOLIS IODIDUM.—U. S.—Thymol iodid, much better known by the formerly trade-marked name "Aristol," is a condensation product of two molecules of thymol with two atoms of iodine, and more properly, therefore, should be designated by its true chemical title, di-thymol di-iodid. This preparation, which really belongs to the phenol group of iodine compounds, has met with a better reception than many of the other iodoform substitutes. It is probable, now that the patents have expired on aristol and the substance is available at much more reasonable prices, that its popularity and use will be extended still further. This, however, is problematic. Schmiedeberg specifically states that aristol, isophan, soziodol, picro, loretin and antiseptol, all of which contain iodine, are not more actively antiseptic than are the corresponding iodine free compounds, while the latter are, of course, much less expensive. Since the number of possible combinations of this type is practically unlimited, we will do well to exercise circumspection in accepting those which appear from time to time.

PHENOL.—U. S.—Acidum Carbolium (U. S. P. 1890) is hydroxybenzene, and may be obtained from coal tar by fractional distillation and subsequent purification, or may be made synthetically. In its pure state it occurs as colorless, needle-shaped crystals, or as a white crystalline mass.

PHENOL LIQUIDACTUM.—U. S.—Liquified Phenol, Liquid Carbohc Acid, contains from 85 to 89 per cent. of absolute phenol, and is the form in which this substance is usually seen and used.

Phenol or carbohc acid is now used as an antiseptic dressing for wounds very much less frequently than it was some years ago, because of the danger of poison due from absorption. It may be applied in the form of a 2 per cent solution in water; stronger solutions are used, but many cases of gangrene

1. An agreeable, and at the same time efficient, mouth wash is obtained by mixing equal parts of aqua hydrogenii dioxidi, liquor antisepticus* (U. S.) and a saturated solution of potassium chlorate.

have followed the use of even dilute solutions on the extremities, particularly the hands, for a continued length of time.

A sharp distinction is to be drawn between the anesthetic and antiseptic uses of phenol. Solutions of phenol in oil, or mixtures with fats, are excellent anesthetics when brought in contact with painful surfaces or wounds, but they possess very little antiseptic action, because phenol is more soluble in fats and oils than in water or weak saline solutions, hence it does not leave the oil to penetrate the bodies of bacteria, without doing which it does not injure them.

Practically the same holds true of its affinity for alcohol, and it is for this reason that alcohol is such an excellent antidote for carbolic acid, externally as well as internally. The absorption of phenol is followed by its appearance in the urine, which usually becomes dark greenish or nearly black in color.

CRESOL.—U. S.—and its more desirable form:

LIQUOR CRESOLIS COMPOSITUS.—U. S.—Compound Solution of Cresol, has been mentioned under general disinfectants. The latter compound has been extensively used, particularly in the form of one or the other of the numerous proprietary preparations, as a local disinfectant and also as an antiseptic. The saponaceous properties of this particular preparation make it very useful in a variety of instances in which a detergent action is to be attained in addition to the disinfection.

THYMOL.—U. S.—This is a phenol occurring in the volatile oil of *thymus vulgaris* and in some other volatile oils. It possesses strong antiseptic properties, but its comparative insolubility in water, 1 in 1,100, has interfered materially with its extended use. Thymol iodid, the only official combination of thymol, has been referred to in connection with iodoform substitutes.

An ideal disinfectant, or antiseptic dressing for wounds, should act strongly on the living protoplasm, should be slowly absorbed, and should affect the central nervous system but slightly after absorption. Phenol has the disadvantage of being rapidly absorbed and of profoundly affecting the central nervous system. Thymol, being but slightly soluble in water, but volatile at ordinary temperatures, is slowly absorbed, and, as its excretion keeps pace with its absorption, there is little danger that it will exert a poisonous action when used locally.

RESORCINOL.—U. S.—Resorcinum (U. S. P. 1890), a diatomic phenol that is usually referred to by its popular name, resorcin, was at one time extensively used in dermatologic practice, but is now seldom employed except for scalp diseases and sometimes internally.

PYROGALLIC ACID.—U. S.—This is better known as Pyrogallol Acid and is a triatomic phenol, sometimes used in dermatologic practice.

ACIDUM SALICYLICUM.—U. S.—Salicylic Acid has been used to some extent as a local antiseptic, particularly in the form of dusting powders, diluted with talcum, zinc oxide or boric acid. Salicylic acid is used extensively in dermatologic practice, particularly in the form of ointment. It is only slightly soluble (1/310) in water.

The practice of dermatology involves a special knowledge of antiseptics, and the subject can be given only general consideration at this time, so that we must content ourselves with little more than a simple enumeration of some of the official substances that are used, merely suggesting the number and variety of the available materials.

PICIS LIQUIDA.—U. S.—Tar, a product obtained by the destructive distillation of the wood of one of several species of *Pinus*, has been widely used in the treatment of skin diseases, usually in the form of an ointment.

UNGUENTUM PICIS LIQUIDE.—U. S.—Tar ointment contains 50 per cent. of tar.

OLEUM CABBINUM.—U. S.—Oil of Cade, or Oil of Juniper Tar, is a product of the dry distillation of *Juniperus Oxycedrus* and is closely allied to tar, being used in the same way.

BALSAMUM PERUVIANUM.—U. S.—Balsam of Peru has already been noted under expectorants. Its antiseptic properties are probably due to the benzoic and cinnamic acids which it contains. It is used in dermatology, either in ointment or in collodion.

NAPHTHALENUM.—U. S.—Naphthalene or Naphthalin and **BETANAPHTHOL.**—U. S.—Naphtol, are used in dermatologic practice, though the former, at least, has practically fallen into disuse for medicinal purposes.

Among other substances having antiseptic properties, used locally, is

SULPHUR PRECIPITATUM.—U. S.—Precipitated Sulphur. This and the other official forms of sulphur have been mentioned in connection with cathartics. Sulphur constitutes a most important agent in the treatment of a number of skin diseases. It is applied either in the form of lotions or of ointments. For the former, precipitated sulphur is usually preferred, while in ointments either

SULPHUR SUBLIMATUM.—U. S.—Sublimed Sulphur, or

SULPHUR LOTUM.—U. S.—Washed Sulphur is used. In the official

UNGUENTUM SULPHURIS.—U. S.—Sulphur Ointment, 15 per cent. of washed sulphur is directed to be used. This ointment is now only half the strength of that formerly official and is, therefore, better suited as a mildly stimulating antiseptic application.

SODII THIOSULPHAS.—U. S.—Sodium Thiosulphate, better known as Sodium Hyposulphite, is another useful antiseptic that is now little used medicinally, except in dermatology. It is freely soluble in water and is usually prescribed in the form of a lotion. It is said to be particularly useful in the destruction of parasitic fungi.

GLYCERINUM.—U. S.—Glycerin is not alone useful as a mild antiseptic, but is also extensively used as a vehicle for many other substances in the treatment of skin lesions.

GLYCERITUM AMYL.—U. S.—Glycerite of starch is a preparation that was introduced many years ago to serve as an ointment base in cases in which lard or fat might prove objectionable.

Mercurials.

HYDRARGYRI IODIDUM RUBRUM.—U. S.—Red Mercuric Iodid or Bimiodid of Mercury is the most active of all the official germicides and antiseptics. It is comparatively expensive, however, and is only slightly soluble in water.

HYDRARGYRI CHLORIDUM CORROSIVUM.—U. S.—Corrosive Mercuric Chlorid, Bichlorid of Mercury, Mercuric Chlorid, or, more popularly, Corrosive Sublimate, is by far the most popular and most generally used of all local chemical disinfectants and antiseptics. It is extremely poisonous and many fatalities have occurred from its use, even in the vagina and in the washing of wounds. Gauze impregnated with a solution of mercuric chlorid is often placed over small or closed wounds to prevent the access of bacteria. It is widely used as an antiseptic and disinfectant, but it is extremely caustic and can not be applied to mucous membranes and to open wounds except in very dilute solutions, for fear of absorption.

Mercuric chlorid is slowly but completely soluble in 13 parts of water and in 3 parts of alcohol. The solubility of this substance in water is much facilitated by the presence of other soluble chlorids. This fact has been utilized in the preparation of the commercial tablets of mercuric chlorid that are sold for making antiseptic solutions. These tablets usually contain about 0.5 gm. (7.5 grains) each of mercuric chlorid and ammonium chlorid, the sal alembroth of the alchemists, which, when dissolved in 500 c.c. (1 pint) of water make a solution of 1 to 1,000. This solution is useful for the disinfection of the hands, for walls and floors and for many fabrics that are not injured by water.

Mercuric chlorid attacks metals and therefore must be avoided with metal instruments. It is a very popular insecticide and a number of the mercurials are used as parasitocides, notably for pediculi. For this purpose, however, the various ointments of mercury are preferable.

UNGUENTUM HYDRARGYRI.—U. S.—Mercurial Ointment, contains 50 per cent. of mercury.

UNGUENTUM HYDRARGYRI DILUTUM.—U. S.—Blue Ointment, a new addition in this edition of the Pharmacopœia, contains 33 per cent. of mercury and conforms more closely to the proposed international standard for mercurial ointment. Another ointment that is sometimes used as a parasiticide is

UNGUENTUM HYDRARGYRI OXIDI RUBRI.—U. S.—Ointment of Red Mercuric Oxid, or Red Precipitate Ointment, containing 10 per cent. of red mercuric oxid.

Antisepsis of the Mucous Membranes.

The antisepsis of the mouth is important, not only because of the infectious diseases pertaining to it, but also because of the excellent opportunity that is afforded to micro-organisms to multiply there in enormous numbers on the particles of food in the cavities of teeth or wedged between them. That this is true is shown by the putrid smell acquired by particles of meat which remain but an hour or so in the mouth. The extent to which bacteria may increase may be inferred from the calculation, given by Novy, that 30,000,000,000 contain less than one-sixth of a milligram (1/400 grain) of organic matter.

The main factor in securing antisepsis of the mouth is cleanliness. If the teeth are carefully cleansed and all organic matter removed, the bacteria have less on which to thrive, and mild antiseptics then fully suffice to keep the number within bounds.

LIQUOR ANTISEPTICUS.—U. S.—Antiseptic Solution is a new addition to the Pharmacopeia, containing 2 per cent. of boric acid with aromatic antiseptic volatile oils. It is designed to be used as a mild antiseptic lotion or wash.²

The official antiseptic solution is also useful as a gargle, preferably diluted with equal quantities of water. The use of hydrogen dioxide as a spray or gargle has been mentioned, also its use in connection with the official antiseptic solution.

POTASSII CHLORAS.—U. S.—Potassium Chlorate, while not a particularly active antiseptic, has long been favorably known to be a desirable addition to gargles and mouth washes. It is soluble in 16 parts of cold water and is generally used in saturated solution, from which traces of chloric acid may possibly be liberated. Alum and boric acid are also useful as gargles.

After the use of any of these gargles the mouth should be well rinsed with water to prevent injury to the teeth.

The antisepsis of the nasal passages is usually accomplished by thorough cleansing with warm saline solution (0.9 per cent.), nine grams (135 grains) to a liter (quart) of water, or by a mild alkaline solution made by adding nine grams (135 grains) of sodium bicarbonate to the saline solution just mentioned, after which a mildly antiseptic solution, such as the official, is used as a spray or douche, or, in lieu of this, one-tenth of 1 per cent. of phenol may be added to the saline douche, but the latter is not recommended as a routine practice.³

It may be permissible here to enumerate some of the substances that have been or are used as mild antiseptic applications to the mucous membranes.

ACIDUM BORICUM.—U. S.—Boric Acid, generally referred to as Boracic Acid, is quite free from toxicity. It is soluble in about 16 parts of water and is but slowly absorbed.

GLYCERINUM BOROGLYCERINI.—U. S.—Glycerite of Boro-

glycerin, contains 30 per cent. of boric acid and has the same uses.

SODII BORAS.—U. S.—Sodium Borate, or Borax, has an alkaline reaction and is sometimes preferred to boric acid on this account. It is soluble in sixteen parts of water.

SODII CHLORIDUM.—U. S.—Sodium Chlorid, common table salt, has been in use as an antiseptic from time immemorial, and the only reason we have for presenting it here is to call attention to the fact that the Pharmacopeia recognizes it as a valuable article of the materia medica and provides certain standards and tests for purity.

SODII PHENOLSULPHONAS.—U. S.—Sodium Phenolsulphonate, the Sodium Sulphocarbolate of former editions of the Pharmacopeia, is another mild antiseptic that has limited but well-defined uses.

Practically all the salts of the alkalis have well-defined antiseptic properties, but it is obviously not necessary to recount all of them at this time.

Complete disinfection of the nose, mouth, throat, vagina and urethra is not practicable, and is not even necessary; the main thing to be sought is the cleansing of those regions from pus and organic matter on which bacteria thrive. Mucous membranes decompose the solution of hydrogen dioxide with such copious evolution of oxygen that it can not be used in the nose, and because of this rapid action by the mucous membrane itself, a large amount frequently repeated is necessary to completely disinfect such cavities.⁴

The antisepsis of the eye is confined largely to the use of camphor, boric acid and sodium borate. In virulent affections more active antiseptics are sometimes indicated; in these cases weak solutions of mercuric chlorid, copper sulphate, zinc chlorid, silver nitrate or formaldehyd are used. These substances, however, are all extremely irritating and great caution is required. Their use by the general practitioner is not advised.⁵

Some years ago J. Stilling recommended the use of the anilin colors, more especially pyoktannin blue and pyoktannin yellow, as weakly antiseptic applications to the eye. Pyoktannin yellow is still used to some extent either as powder, pencil or in watery solution.

Burns or scalds resulting in destruction of the skin should be treated antiseptically. Treves directs that the burn be washed with a solution of hydrogen dioxide and then with a solution of boric acid; the vesicles are then opened with an aseptic needle and the surface dusted with iodoform and dressed with aseptic cotton.

LINIMENTUM CALCIS.—U. S.—Lime Liniment, or Cayton Oil, so called from the name of the iron works in England where this preparation had its origin, consists of equal parts of lime water and linseed oil. It has long been in use as a popular dressing for superficial burns and constitutes a readily applied and effective non-antiseptic remedy that rapidly allays the accompanying pain. If there has been extensive destruction of tissue, this remedy should be avoided, as it is not alone difficult to remove, but also forms a covering beneath which bacteria may proliferate safe from the reach of antiseptics.

POTASSII PERMANGANAS.—U. S.—Potassium Permanganate,

4. For use in the vagina, where a simple detergent and antiseptic action is sought, the official *Liquor Cresolis Compositus* in 0.5 to 1 per cent. solution will be found to be all that is required. When an astringent effect is desired the following formula for an antiseptic astringent powder will be found to answer the purpose very well.

R.	Sodi boratis	℥i	40
	Alumen exsic.	℥ss	40
	Thymol.		
	Phenol.		
	Eucalyptol.		
	Olei gaultherie, aa.	℥ss	5

M. Sig.: A heaping teaspoonful to be dissolved in one liter (1 quart) of hot water, to be used as a douche.

5. The method of using boric acid in the eye varies greatly, but usually a 2 per cent. solution of boric acid in equal parts of distilled water and camphor water will be found to be sufficient. When it is desired to use sodium borate in connection with boric acid the following will be found satisfactory:

R.	Acid boric	℥ss	xv
	Sodi boratis	℥ss	xxx
	Aqua dest.		
	Aque camphorae, ℥ss		50

2. The official antiseptic solution is slightly acid. When an alkaline antiseptic mouth wash is desired it will be well to use the "Alkaline Antiseptic Solution" of the National Formulary. Either one of these preparations can readily be prepared by any trained pharmacist. They are very inexpensive and should be given the preference over the various nostrums that are not alone exploited as local antiseptics, but are also advertised as sure cures for a very large number of intestinal disorders. The working formula for the alkaline antiseptic solution is as follows:

Potassium bicarbonate	℥i	32
Sodium benzoate, aa	℥ss	40
Borax	℥ss	40
Thymol	℥ss	40
Eucalyptol		
Oil of peppermint, ad.	℥ss	40
Oil of wintergreen	℥ss	40
Tincture of eucbear	℥ss	40
Alcohol	℥ss	40
Glycerin	℥ss	40
Water, sufficient to make	℥ss	40

3. The pharmacopeia of the German Hospital, Philadelphia, contains a formula for an alkaline antiseptic tablet that has found favor with some. It contains 0.25 gm. (about 4 grains) each of sodium bicarbonate, sodium borate, sodium chlorid and sodium phosphatule, with 0.005 gm. (about 0.1 minim) of oil of cinnamon. One of these tablets (the same mixture can also be directly in powder) is to be dissolved in six tablespoonfuls of recently boiled water and used as a wash for the nose.

already referred to under the head of general disinfectants, is often considered to be devoid of antiseptic properties because of the readiness with which it oxidizes all organic matter. It is true that potassium permanganate is readily decomposed by the organic matter with which it first comes in contact, and that it would be unusual indeed to find bacteria the only form of organic matter present in any one case. When we remember, however, that a very large number of bacteria represent but an infinitesimally small amount of organic matter, we will appreciate why potassium permanganate is capable of destroying vast numbers of micro-organisms in those cases in which its action can be confined to them.

This substance finds its greatest usefulness as a local application in rendering foul ulcers odorless. For this purpose a fairly strong solution, 2 per cent., is freely used as a wash. Much weaker solutions are sometimes used with great benefit as urethral irrigations in gonorrhea and as vaginal douches. A hot 1 per cent. solution of potassium permanganate will be found extremely useful as a deodorizer for instruments after use in the vagina while awaiting sterilization. Potassium permanganate destroys some alkaloids much more quickly than others, e. g., morphin more readily than strychnin. It can not enter the circulation, hence when swallowed it can act only on the substances found in the stomach. Obviously it is not suited for hypodermic injections.

Clinical Reports

SARCOMA IN A YOUNG CHILD.

FRED S. SPEARMAN, M.D., C.M.

WHITING, IOWA.

A number of interesting points are to be noted in connection with the following case:

1. The extreme youth of the patient, so that the malignant growths or the causes favoring their production must have been present almost, if not quite, from the time of birth.

2. The occurrence of tumors in several generations of the patient's family, showing an apparent hereditary tendency to neoplasms.

3. The marked displacement of the heart and spleen from their normal locations as the result of pressure by the tumor in the lung.

Patient.—E. S., born Nov. 15, 1902, male.

Family History.—Parents are both healthy; their occupation farming. A brother and sister are also in good health. Father's father and grandmother died from carcinoma. Both died years before the birth of my patient. Father's mother had an epulis removed about six years ago. Another growth came on another portion of the gums a year or so later, but disappeared of itself.

Precious History.—The child was never very robust, but had had no serious illness before the present one.

Present Illness.—I saw the patient for the first time on July 10, 1905. The parents stated that a little more than a year previously they had noticed an enlargement in the right side of the boy's scrotum. This had grown steadily but slowly for the first eight or nine months, but since then more rapidly. It did not seem to be painful at any time, but lately, on account of its increasing bulk, had caused some inconvenience, and the child appeared slightly nauseated at times.

Examination.—This showed a tumor of an ovoid shape about half the size of one's fist in the right side of the scrotum. It was solid, smooth, not translucent, no fluctuation was present or nodules felt, and there was no tenderness on pressure. The skin over the tumor was normal, there was no redness or sign of ulceration. The left testicle could be felt in the upper part of the scrotum and was of normal size. The child was bright and intelligent. He was of rather slender build and his complexion was tanned. Evidences of rachitis were present, as shown by a rather large head, somewhat box-shaped, and a

slightly developed rosary, which became more pronounced as the case progressed. I advised operation.

Operation.—A trocar was introduced, but no fluid obtained. An incision about one and one-half inches long was made through the superficial tissues into the growth. This was of a reddish-gray color, homogeneous, was friable, of about the consistency of rather old bologna sausage, and was adherent to the tunica, which were considerably thickened. I got out the growth piecemeal, removing portions of the tunica also. A small quantity of clear fluid escaped when the upper part of the tumor was removed. Chloroform was the anesthetic used, and I noticed that the child did not breathe well toward the last, although the heart's action was fairly good throughout. Recovery was uneventful, and I let the parents do the dressing after the first week. There was a slight serous discharge for a time from the wound, but it had practically healed by July 26.

I sent the tumor to Dr. G. S. Browning of Sioux City for examination, who pronounced it a fibrosarcoma containing a large proportion of fibrous tissue.

After the operation the boy's general health improved for a time, his appetite gained and he played more with the other children.

Further History.—August 10 the parents brought him to me again. They said that he had seemed listless for a few days, caring neither to eat nor play and showing some nausea at times. His skin and conjunctivae were slightly jaundiced. As the weather was very hot at the time, I attributed his condition to this and did not examine him closely, but gave him a calomel purge and a bitter stomachic mixture. August 13 he was again brought in, as he was no better. Jaundice was more marked, and the mother informed me that the nausea was increased and that he had complained at times of pain in the left side in the region of the lower ribs.

Examination.—Percussion showed the area of liver dullness extended nearly an inch below the costal margin. On the left side there was an area of dullness reaching from about the lower level of the fourth rib in the anterior axillary line to an inch below the border of the ribs. This dullness extended to the spine behind and nearly to the median line in front. On palpation a firm mass could be felt below the ribs. Auscultation revealed an absence of breath sounds over the lower area of pulmonary dullness and faintness in the upper portion. There was less expansion of the left side of the chest. The apex beat of the heart was displaced nearly to the left border of the ensiform cartilage. Considerable meteorism was present. Pulse was about 140 and temperature 99. I suggested the possibility of an internal growth similar in nature to that occurring in the testicle, and judged from the physical signs present that the liver and spleen were probably involved, as well as the lung. An examination of the urine made a few days afterward was negative. In view of the autopsy findings, later examinations, which I omitted to make, would no doubt have revealed renal involvement.

The patient was put to bed on liquid diet, and under fair-sized doses of calomel the jaundice disappeared to a great extent in a short time. At first the stools were bile-stained, but afterward became slate-colored, remaining so until the end. There was considerable trouble throughout on account of meteorism, requiring constant use of purgatives and enemata. The dullness extended on both sides quite rapidly, and the child's respiration became continually more embarrassed. An aspirating needle, introduced into the left chest on August 21, brought only a small amount of bloody fluid. The following day Dr. R. E. Coniff of Sioux City saw the case with me and agreed in the probable diagnosis of an internal sarcoma. A blood count made by him showed the white cells to number 35,000 to the cmm.

At this time there was a marked bulging out of the ribs on the left side behind and laterally, although the intercostal spaces did not bulge. The dull area on both sides was nearly two inches below the costal margin and the liver was plainly palpable. The outlines, both of it and the tumor on the left side, could be seen through the abdominal walls. On deep pressure on the left side of the abdomen at the level of the umbilicus a hard body could be felt, which I thought to be a nodule in the large intestine. The apex beat was displaced to

within one inch of the right nipple and about one-half inch below. To and fro murmurs were present. They were harsh, prolonged, and of a somewhat ringing or humming quality, giving the impression of tenseness, like the sudden stretching of an elastic band. Pulse rate was about 160 and very weak, respirations over 40, no rise in temperature. There was slight puffiness of the eyelids, especially the right one, and the superficial veins on the right side of the neck and over the liver were distended. Priapism was present throughout the latter part of the case, being more marked after micturition. A condition of phimosis present may have had something to do with this, as well as the splenic involvement. There was no urinary suppression at any time, although the quantity was decreased. The child became continually more emaciated, his breathing more and more difficult, as toward the last air entered only the very apex of the left lung, accessory muscles of respiration were brought into play, the heart's action became faster and weaker, and on September 1 he died.

Autopsy.—This was performed the next day. An incision was made from the ensiform cartilage to the umbilicus through the abdominal wall, which was very thin. The diaphragm could be seen bulging downward on the left side and was very tense on account of pressure of the growth from above. On incision the tumor was found closely adherent to the diaphragm, which formed its base. It was of a spongy, stringy consistency and nearly all of the left lung was involved. The mass was softer in the center, being almost semi-fluid, and portions removed were of a grayish color, slightly tinged with pink. The spleen was not much enlarged and was shoved down to the level of the umbilicus. The liver extended down to the same level, was very friable, and of a lighter color than normal, and yellow patches and streaks were present throughout. A whitish fluid escaped from the cut or broken surfaces on squeezing. The kidneys were enlarged and engorged, being of about the same color as the spleen.

Specimens of the different organs were sent to Dr. Henry Albert, state pathologist, of Iowa City, for examination. He reported that the pulmonary growth belonged to the class of endothelial sarcoma, although the arrangement of the cells was such that many pathologists would call the growth a carcinoma. The liver showed subacute inflammation. The spleen had distinct areas of inflammatory changes, with infiltration of round cells, and the kidneys manifested a distinct acute diffuse nephritis. Neither liver, spleen nor kidneys revealed any evidences of malignancy, however.

PNEUMONIA COMPLICATED BY MENINGITIS.

W. H. AXTELL, M.D.

Surgeon Northern Pacific Railway.
BELLINGHAM, WASH.

I report the following because of its infrequent occurrence:

History.—Mrs. W., aged 32, family history negative, very sparely built, has one son 5 years of age, and has had no illness since childhood. The present illness began Nov. 28, 1904. In the morning she had a sharp chill, followed in the afternoon by high temperature and a slight pain in the right lower chest. During that night and the forenoon of the next day the pain became very much augmented.

I saw her at 3 p. m. on November 29. Her temperature then was 105 1/5; pulse, 140; respiration, 36 and panting in character; she was cyanotic. Auscultation revealed crepitant rales in the lower lobe of the right lung in the axillary line. The area of dullness on percussion was about the size of a silver dollar. The pleurisy extended over a greater part of the right lateral chest. There was slight delirium when partially asleep.

Diagnosis.—Lobar pneumonia, with pleurisy.

Course of Disease.—She was moved to the hospital the same evening. The course of the disease was tempestuous, but followed that of a typical pneumonia, the crisis occurring on the

eighth day. On the third day slight meningeal symptoms developed. These began with a very sharp frontal headache, the pain of which was very distracting. The pupils, at first contracted, were dilated after the fourth day. There was some rigidity of the muscles at the back of the neck, but no convulsive movements. The heart showed no signs of depression or of inflammation. The delirium, at first mild, increased in severity until, on the day of the crisis, she became a raving maniac.

Osler says: "Meningitis is usually associated with endocarditis and occurs in 8 per cent. of fatal cases and endocarditis in 25 per cent. of all cases."

This woman had no heart complications whatever. Two days before the crisis, when the temperature was the highest, the patient became so violent that it required the combined effort of two nurses, night and day, to restrain her. On the twenty-first day of the disease she was discharged from the hospital, thoroughly convalescent. Up to the present time her mental condition has remained normal and there has been no evidence of insanity. The treatment was simply supportive. The ice cap was applied for the relief of the head symptoms and cool spongings for the temperature.

POINTS OF INTEREST.

1. Complication of meningitis without endocarditis.
2. The violent nature of the disease itself. (The meningitis in no way retarded or altered the usual course of the disease or lengthened its duration.)
3. The heart during the whole course of the disease and without special treatment showed very little depression.
4. A study of the chart shows a marked similarity in the variation and fluctuation of the delirium, temperature, pulse and respiration.
5. Of the many authorities consulted, Osler is the only one who particularly mentions meningitis as a complication of pneumonia. Tyson in his recent work simply calls attention to Osler.
6. Complete recovery.

SATURDAY, MARCH 3, 1906.

THE SYNTHESIS OF PROTEIDS.

When the average medical man who has not had a recent training in chemistry sees an article on the modern progress in the study of the proteid molecule, he is generally of the opinion that the contents will be beyond the range of his chemical knowledge and passes the matter by. The fundamental principle of the structure of the proteid molecule, however, is not beyond the comprehension of the man who possesses but very little knowledge of chemistry. The same is true of the principles underlying the experiments of Fischer and Curtius in the synthesis of proteids. As these studies in proteid chemistry have produced what are probably the most important advances made in the fundamental principles of physiologic chemistry and biology for many years, we feel it our duty to attempt to explain at least the essential principles of the subject to our readers.

The first insight into the composition of the proteid molecule was obtained by studying the products obtained by splitting it up by means of various agencies, such as the digestive ferments, boiling acids, superheated steam. After passing through stages in which albumoses and peptones are produced, we eventually obtain a collection of simpler substances which are dissimilar to the original proteids. The longest known among these substances are leucin and tyrosin, but they are merely two of a great number of similar bodies, nearly twenty of which have already been isolated in pure condition and thoroughly identified. The important thing to bear in mind about these substances is that they are the elementary components of the proteid molecule, from which it is built up. The German writers usually refer to them as the *Bausteine* (building stones) of the proteid molecule. It has been firmly established that they exist, ready formed, in the proteid molecule, and that the process of digestion by trypsin, or by boiling acids, or by any other means, merely consists in separating these building stones from one another, so that the entire structure falls apart, and in this way we obtain the single components of which it was formed.

The next thing to take into consideration is the chemical structure of these substances, and here lies the key to the problem, for we find that each one of them is possessed of a common chemical grouping to which it

owes its most essential properties. For example, let us examine the structural formulas of a few of the *Bausteine*.

Leucin has the formula, $(\text{CH}_3)_2\text{C}=\text{CH}-\text{CH}_2-\text{CH}-\text{COOH}$

Tyrosin is $\text{HC}(\text{HOC})(\text{CH}_2-\text{CH}-\text{COOH})$

Cystin $\text{CH}_2(\text{SH})-\text{CH}-\text{COOH}$

It will be observed that each building stone is an acid, which has an NH_2 group (amido group) substituted for a hydrogen atom on the carbon nearest the acid radicle (COOH), and hence they are called amino acids. It makes no difference what the rest of the radicles are, whether they are simple chains (leucin) or members of the aromatic series (tyrosin) or sulphur-containing bodies (cystin), without exception, this relation of an NH_2 group to an acid radicle is constant, as in this formula:

Radicle - $\text{CH}-\text{COOH}$

Through this arrangement every one of the constituents of the proteid molecule is provided with a group with a strong basic character (NH_2) and a group with a strong acid character (COOH), and hence it is possible for them to unite with each other in indefinite numbers and, because of the great variety of individual substances, in practically an almost infinite number of combinations. It is believed that it is in just this way that the proteid molecule is built up.

Now, because of the existence of both acid and basic characters in the *Bausteine*, it is possible to make them unite with one another again, after they have been separated during the process of splitting of the proteid molecule. (This process of splitting is called "hydrolysis," because, in the reaction, water is taken up by the substances.) By artificially uniting *Bausteine* in this way Curtius in Heidelberg, and more particularly Emil Fischer in Berlin, have attempted to rebuild a proteid molecule. The bodies so formed are called "polypeptides," and the process by which they are made may be illustrated by showing the reaction by which the simplest one of them, glycyl-glycin, is formed through the union of two molecules of glycocoll, the simplest of the *Bausteine*.

It should be noticed that here, in the building-up process, water is split off, which corresponds to the fact that water is taken on (hydrolysis) in the breaking-down process. By means of such reactions it has, up to the present time, been possible to build up large molecules containing as many as six or seven of the *Bausteine*, and it is only a matter of time, labor and money before much larger molecules may be formed.

It must not be imagined that the structure of the complete proteid molecule is simply a long straight string of amino acids joined only in the same way as the components of glycyl-glycine. The existence of diamino acids, of benzene rings, of hydroxyl groups as in serin or tyrosin, of ring compounds as pyrrolidin carbonic acid, of substances with two acid groups as glutaminic and asparaginic acid, adds complications to the formation until it is impossible to estimate just how all the various building stones may be arranged. One must also bear in mind the size of the proteid molecule, which Hofmeister has estimated (for serum albumin) as having a molecular weight of 10,166, with an empirical formula of $C_{430}H_{720}N_{116}S_6O_{140}$, and for hemoglobin the molecular weight has been estimated at 16,669. Within such a "giant molecule" there is room for variety almost beyond computation.

The question that the practical man will probably ask at this point is: "Are these polypeptids proteids; has a proteid molecule yet been formed?" The answer to that must be as follows: Polypeptids are not proteids in the sense that egg albumin or fibrin are; they are crystalline, soluble substances, and much smaller in size and molecular weight than even the peptones, which are the smallest divisions of the proteid molecule that retain most of the proteid characteristics. They are, however, probably intermediary between the peptone and the amino acids into which it splits, and they possess among others the following very important characters that are exhibited by proteids: First, they give the well-known biuret reaction, by which we usually distinguish peptones; second, and most important, they are split up by trypsin, exactly as are the proteids, liberating the *Bausteine* again. As the enzymes are such specific substances, acting only on molecules, with very specific natures and structural configuration, this is very strong evidence of the close relation of these synthetic products to the larger molecules that are ordinarily called proteids.

It should also be borne in mind that neither Emil Fischer or any other scientist expects in this way (or in any other way) to "create life in the test-tube." That is a fantasy that exists only in the minds of the ill-informed. It is hoped, indeed expected, that true, typical proteids may eventually be synthesized, but the production of a proteid is in absolutely no way comparable to the production of a living cell.

THE PARASITIC ORIGIN OF MALIGNANT NEOPLASMS.

The number of observers who have discovered the cause of malignant neoplasms in the past ten or fifteen years almost equals the number who have found the parasite of syphilis. Bacteria, yeasts, protozoa, all the different varieties of minute animal and vegetable life, have been, in turn, incriminated only to be dismissed from the bar of professional opinion with the verdict of not guilty, or the more canny one of "not proven." The

subject seemed to have been attacked from all possible sides and tested in all possible ways, but, judging from the recent work of Schmidt,¹ methods of attack are still open.

If cancers and other malignant growths are due to parasites, there surely must be some reason why we can not see these micro-organisms. Past experience with other parasites furnishes a variety of explanations. The parasite may be ultramicroscopic, it may be unstable by methods at present known, or it may so closely resemble the cells of the host as to be indistinguishable. Schmidt thinks that he has discovered the parasite in an ameba which he has been able to observe in carcinoma in various phases of its existence. Amebas have a definite cycle of development, and among other things, at a certain stage in their development, require an intermediate host, which may be an insect or some low form of vegetable life.

The researches of Schmidt, who, reasoning from analogy, concluded that such an intermediate host must be present, led him to the discovery that a certain form of mould obtained from malignant neoplasms contained bodies corresponding in morphology to amebas in certain stages, which were not present in the same variety of mould obtained from other sources. The mould and the enclosed parasite, under favorable circumstances, could be observed to develop, and in their development went through entirely dissimilar processes.

The inoculation into animals of moulds obtained from new growths led to the formation of malignant neoplasms in a percentage of cases much too high to have been due to coincidence. In all the inoculated animals in which positive results were obtained the growths appeared at the point of inoculation and after a period of incubation which was approximately the same in all instances. In some of the experimental cases the tumors gave rise to metastases, in others they did not; in all cases they were histologically of a malignant type, either carcinomata or the so-called Jensen's tumor.

After the discovery of the parasite Schmidt reasoned that if it were really responsible for malignant neoplasms it should, if inoculated into subjects with such growths, give rise to a reaction similar to that observed after the administration of tuberculin to a patient with tuberculosis. With this idea in view, a number of individuals suffering from inoperable new growths were inoculated subcutaneously with dead cultures of the organism. In nearly all cases the result was a rise in temperature, accompanied in some instances by very marked local reaction. The amount of dead culture injected varied from one-tenth of a milligram to five milligrams, and the injections were always made at a point some distance from the new growth. In at least one instance failure to react led to a diagnosis of a non-malignant disease, the diagnosis being confirmed by operation.

1. Münch. med. Wochft., 1906, liii, 162.

These observations are certainly striking, and the work is along hitherto untraveled lines. Great possibilities are opened up, for, if patients with malignant neoplasms react to injections of Schmidt's organism, it should be possible to cure the disease by the inoculation of the attenuated virus according to the principles laid down by Wright for the treatment of certain bacterial diseases. So far as Schmidt's observations on human beings are concerned, we think it can fairly be said that as yet a sufficient number of tests have not been made. We must acknowledge the suggestiveness of the work, however, and hope that it will soon be substantiated.

HEART BLOCK AND THE STOKES-ADAMS SYNDROME.

The cause of the heart beat, and the path which is taken by impulses passing from the auricles to the ventricles, has been a matter of controversy for years. The physiologists have practically always been divided into two camps regarding the matter, one group insisting that the transmission of the heart impulse takes place through the nervous system, the other that it occurs by means of muscular tissue. Until within two or three years the former group seemed to have a little the best of the argument, but the discovery by His, Jr., in 1903, that there existed a muscular band which connected the auricles with the ventricles put an entirely new face on the matter. This bundle, which is now quite generally spoken of as the bundle of His, is, in man, a narrow band 18 millimeters long, 2.5 millimeters wide, and 1.5 millimeters thick. The bundle runs posteriorly in the septum of the ventricles, from which it passes into the musculature of the right auricle and its valves.

The experimental demonstration that the bundle transmits the impulses from the auricles to the ventricles has been made by His, Humbert, and more recently by Erlanger,¹ whose interesting experiments should be read by all students of heart disease. Without going into detail regarding the methods of experimentation, it may be stated that by varying degrees of compression of the bundle of His all stages of heart block, i. e., interruption of the transmission of impulses from the auricles to the ventricles, may be obtained. Slight compression results merely in an increase in the inter-systolic pause; more marked compression produces intermittency in the ventricular contractions, and complete compression causes the auricular and ventricular contractions to occur independently of one another. The experiments also showed that, while the accelerator cardiac nerves are not influenced by heart block, the vagi lose their control over the ventricles.

The bearing which these observations have on certain forms of heart disease, and especially on the so-called Stokes-Adams syndrome, can not be overestimated. It will be remembered that the cardinal symptoms of this condition are bradycardia, in which the auricles may be

definitely shown to beat more rapidly than the ventricles, and apoplectic or epileptiform attacks. As Erlanger states, all the cardinal symptoms of Stokes-Adams disease may be explained by the effects of heart block. The relation of heart block to slow pulse and disparity of action between the auricles and ventricles has already been made clear in discussing the experimental work. The epileptiform attacks are explicable as the result of anemia of the brain, and are doubtless similar to those seen after hemorrhage in warm-blooded animals. The apoplectic attacks are probably due to venous congestion of the brain, which has long been known to be associated with slow respiration, paralysis of the glottis, and spasmodic symptoms.

A glance at the autopsy protocols of the published reports of cases of Stokes-Adams disease shows at once that, so far, no one pathologic condition has been found as a cause. It is also apparent that in some cases lesions are described which could easily exert pressure on the bundle of His—tumors of the septum, for example. Naturally, up to the present time, there has not been any opportunity to examine this bundle in any large number of cases. We believe that a case of Stokes-Adams disease has recently been reported by Stengel, in which definite disease of the auriculo-ventricular bundle was present, and there is little doubt that similar reports will soon be forthcoming. Some points which have been developed in the treatment of this affection, on purely empirical grounds, are interestingly made clear by the experimental work, especially the disadvantages of digitalis in this affection, and the good results sometimes following the use of iodids. The latter may be partly explained on the ground that the disease of the bundle of His is sometimes syphilitic. Erlanger suggests that atropin, by steadying the pulse, will also be of value in this condition.

OUR DUTY REGARDING "PATENT-MEDICINE" LEGISLATION.

A large majority of "patent medicines" are injurious to the health of the public and the cause of many deaths. We believe this is the opinion of every physician, except the few who are biased by commercial relations. There is not a practicing physician who is not conversant with the deadly nature of some "patent medicines" and who, from his own individual experience, can not bear witness to cases in which harm has resulted from their use. It seems strange, therefore, that our profession is not earnestly supporting the movement for controlling the sale of these preparations.

We have emphasized the fact that it is neither wise nor necessary to oppose "patent medicines" *per se*, and few physicians do so. But there can be no argument against the need of legislation for the protection of the public against fraud in "patent medicines," and especially against those containing such poisons as cocaine, opium or its alkaloids, chloral and acetanilid. And yet

¹ The Journal of Exp. Med., 1906, vol. VIII, 8.

the experience this year in several states emphasizes the fact that physicians are taking practically no interest in the legislation that is being attempted.

In South Carolina they had a very fair bill before the Legislature, but it was killed simply because those who were working for it—as a rule, laymen—were unorganized. The opposition, on the other hand, was well organized by the Proprietary Association of America, and this association was especially in a position to control many of the druggists, as it also partially “controlled” the newspapers with the famous “red clause.” According to the *Journal of the South Carolina Medical Association*, a delegation of druggists visited the capitol to work against the measure, because “if it were passed it would be simply a diversion of the revenue of the traffic into the pockets of dealers in other states, and not a restriction of the sales with protection to the public as was contemplated, and that such a diversion would be not only unjust, but very injurious, to our own drug sellers.” But while the druggists were being used to oppose the measure, physicians were inactive. Referring to this fact, the above journal says: “We are able to comprehend, even if we do not sympathize with, the action of the druggists, but we neither understand nor excuse the indifference of physicians to a measure which concerns one of the most important planks in our platform.”

The druggists seem to have been organized in South Carolina, as they are in other states, by the Proprietary Association, evidently through the N. A. R. D., but we do not believe that a majority of the druggists are opposed to a law regulating “patent medicines.” Most certainly many of those who are opposing such legislation do so at the instigation of the “patent medicine” manufacturers and could easily be won over if physicians would but appeal to them. “We believe,” says the *Journal of the South Carolina Medical Association*, “that their best interests will be served by working in association with physicians and not in opposition. Pharmacists and physicians should be closest friends, as they are mutually dependent and their aims and ideals should be in harmony. However commercial their recent action may indicate them to be, we believe that if we could get together the result would be a better understanding and a higher conception of the duty which they, as well as we, owe the public.”

The journal urges the physicians of South Carolina to give the matter thought and, when the occasion presents itself again, to assist in obtaining the legislation which they know is needed in the interest of public health.

In Iowa a bill is before the Legislature, modeled after the North Dakota law. It is a very conservative bill, and was introduced by Dr. Young, a member of the Senate. The profession of Iowa seems to be as unconcerned in the matter as are the physicians of South Carolina. A correspondent, who has been in touch with what has been going on in the Iowa Legislature, tells us that at the

meeting of the committee on February 16 to consider the bill four different representatives of the “patent medicine” manufacturers appeared before the committee, but that no physicians were present, except those who were members of the Legislature. We are informed that the proprietary men did not make a very good impression on the committee, and felt that there was not much response to their talk, which was largely an attack on the *Ladies' Home Journal* and *Collier's Weekly*. But they were not long in putting their machinery into effect in Iowa, as they did in South Carolina and in other states, with the result that druggists from all parts of the state wrote to the members of the Legislature asking them to oppose the bill, and, of course, such efforts are having their effect. The newspapers responded, too, but not as they did in Wisconsin and in Massachusetts last year. Even one medical member of the House is reported to have weakened when he received several letters from druggists in his district. Those favoring the measure expected some help from the medical profession in Iowa, but, from all reports, received practically none.

From Mississippi comes almost the same story. A bill, also modeled on the North Dakota law, was introduced by Representative Lockwood, not himself a physician. Several medical societies passed resolutions approving the bill, but the members of these societies, having passed the resolutions, evidently considered that they had done their full duty as men and physicians. A correspondent who was on the ground writes:

“Physicians used no influence in favor of the bill, except to pass resolutions indorsing it; they advanced no arguments; they wrote no letters to the committee or to members of the legislature. So much for sins of omission. While the physicians of Mississippi were attending strictly to their private affairs and forgetting the interests of public health the Proprietary Association of America was busy. It sent men up from New Orleans to Jackson to lobby; it manipulated the ‘red-clause’ press (though a number of independent weeklies through the state came out squarely for the bill); it distributed literature. Antikamnia sent a special agent to the spot. (Observe how this ‘ethical’ proprietary shows its true colors when quackery and fraud are threatened.) The retail druggists were stirred up to write to the Legislature, and protests poured in on the committee having the bill in charge. This committee is largely made up of physicians. Mr. Lockwood looked, with some confidence, to a favorable report. He made an error of estimate.

“Now come the sins of commission. The arguments of the proprietary interests and the complaints of the retail druggists were more potent with the physicians of the Committee on Public Health than principle, the honor of their profession or the public health which they were supposed to conserve. The bill was killed in committee, and the four physicians on the committee are said to have voted to kill the bill.”

We hope that the physicians referred to voted to kill the bill because it was not satisfactory, and not because

they were opposed to the regulation of the patent medicine business. We understand that another bill is in course of preparation and will be introduced immediately. We sincerely hope that the physicians on the committee will at least vote in favor of letting it come out into the open, in which case it is likely to pass, because public sentiment is in favor of the proposed legislation. It certainly will if physicians do their full duty.

The fight against fraud in "patent medicines" is on in Maryland, Mississippi, New York, New Jersey, South Carolina, Virginia, Iowa, Ohio, Kentucky and in some other states. In each of these states, we believe, the state society has a committee on legislation. It is the duty of that committee to take the lead in the movement; if there is no committee, then it is the duty of the president of the state association to see that the medical profession in his state is at least given an opportunity to act. If those fail to act who have been appointed or elected to represent and lead the profession in movements in which it is interested, then little successful work may be expected, unless some unusually public-spirited member comes forward and takes the lead.

Our profession claims to act on altruistic motives; here is an opportunity for its members to demonstrate its altruism by work. The movement against the "Great American Fraud" is being made by non-medical men; should we not support them? Is it not our duty to do this? Can we do less than help in this propaganda against the unrestricted greed of those nostrum manufacturers who are not only swindling the people, but undermining their health and who even sacrifice human life to satisfy their greed? The facts recorded on page 666 of this issue concerning one nostrum alone should be sufficient to arouse every physician to appreciate what his duty is.

THE BOSTON SESSION OF THE AMERICAN MEDICAL ASSOCIATION.

The Boston session of the American Medical Association will be the largest ever held. There is no doubt of it. It will be forty-one years since the Association met in New England, and the historical attractions will, of themselves, be sufficient to draw many to the meeting. The members of the profession from New York—city and state—will go as they have never gone before. From the south, the southwest and the extreme west there are more inquiries about railroad rates, accommodations at Boston, etc., than in any other year. New England itself is also being heard from in a way to show that it will be unusually well represented at the session. The officers of nearly all the sections report filled programs unusually early and more evidence of interest in scientific work. While the passenger associations have not acted definitely, those in authority have given assurances that half rates will prevail, with the extension of time to those who want to extend their visit in New England. It is hoped that provisions will be made to accommodate those who want to go by one

route—say by the lakes—and return by another. Many foreigners have already accepted invitations to attend, among them Professor Trendelenburg, Leipzig, Germany; Mr. Reginald Harrison, London, Eng.; Professor von Rosthorn, Heidelberg, Germany; Professor Dührssen, Berlin, Germany, and Professor von Frey, Würzburg, Germany. Hence we repeat: The Boston session of the American Medical Association will be the largest ever held—and the Boston people know it and are acting accordingly. Committees have been working for months making preparations, and they promise good accommodations and a thoroughly interesting and profitable time to all who attend.

THE PHILIPPINE JOURNAL OF SCIENCE.

We are glad to welcome into the journalistic field such a fine periodical as the *Philippine Journal of Science*, the first issue of which has just made its appearance. This journal takes the place of the bulletins formerly issued by the Bureau of Government Laboratories of the Philippine Islands. The periodical is to contain original articles by members of the bureau staff, as well as by others who are doing scientific work in the Philippine Islands and adjacent countries of the Orient. The journal will thus have the unique function of presenting the united scientific results achieved in contiguous countries in the tropics. With the growing interest which is being taken in tropical medicine, it seems certain that a publication of this character will secure a large number of readers. The present issue contains articles on "The Water Relations of the Coconut Palm," by E. B. Copeland; "The Coconut and Its Relation to the Production of Coconut Oil," by H. S. Walker; "The Occurrence of *Schistosoma Japonicum* vel *Cattoi* in the Philippine Islands," by P. G. Woolley, and "A Study of Some Tropical Ulcerations of the Skin with Reference to Their Etiology," by R. W. Strong. The last is illustrated profusely by excellent photomicrographs of histologic sections of the skin. The mechanical work of the journal is excellent. It is announced that the journal will be issued in approximately ten numbers a year.

THE PURE-FOOD BILL.

Rather contrary to expectations, the Heyburn Pure Food Bill passed the Senate February 21 with only four dissenting votes. The constitutional objections to the bill, raised by Senator Spooner, seem rather far fetched and we think he is only making excuses for his opposition. The standard for food and drinks is purity, or at least safety, and a plain statement on the package of what its contents consists; and these ought to be a sufficiently definite standard and certainly within the spirit of the best good for the public. The bill has now to go before the House, and it is openly charged by press-correspondents that a number of votes were given to the bill with the understanding that it would not be disposed of by the House at this session. The friends of pure food must prevent the realization of this ex-

pectation. If the senators were amenable to public opinion, members of the House are still more so; they must reckon with their constituents more directly, and it will be strange if the policy of delay thus suggested can be successfully carried out. There is all the more need, however, that we should not slacken in our efforts to insure the passage of the bill. The whiskey and "patent medicine" interests and the innumerable army of adulterators of all kinds will not be idle. All the influences that have been at work heretofore will now be more active than ever to prevent the passage of the bill or to emasculate it by amendments. Only half the battle has been won, and we may lose all if we allow ourselves to be lulled into a false security by this success. It will not be much trouble or expense for each physician to write to his congressman, asking him to support the pure food bill; just a sentence or two will be sufficient. And if half the physicians of the United States would do this, it would go a long way toward getting a national pure food bill.

AN OBJECT LESSON IN PURE FOOD.

A New York chemist is reported to have treated some of his friends to what he called a "synthetic dinner," each article of food being an artificial substitute for the real thing. It is not stated how well these materials tasted, but it is rather significantly said that after the dinner the chemist's friends joined the ranks of the "pure fooders." As the *Chicago Tribune* aptly remarks, it was an object lesson showing "what kind of meals many of the people of the United States might expect in a few years to be sitting down to three times a day, in the absence of legislation for their protection."

Medical News

ILLINOIS.

Smallpox.—Smallpox in dangerous form is epidemic in Carroll County. Twenty cases are reported in Lanark and 2 in Milledgeville. All lodge meetings and public gatherings have been prohibited in Lanark and the schools have been closed. The 2 cases of varioloid reported in Lincoln have been rigidly quarantined and no new cases have appeared.

Personal.—Dr. R. S. Frisbie, assistant superintendent of the Asylum for Feeble-Minded, Lincoln, has resigned. Dr. J. L. Allegen, Rockford, was assaulted February 14 by William Gleason, whose horse became frightened at Dr. Allegen's automobile. Dr. F. O. Jackman, Bloomington, is suffering with septicemia. Dr. S. P. S. Edwards, Moline, has been elected secretary of the Tri-City Sanitarium.

Chicago.

Personal.—Dr. Palmer Findley has accepted the chair of gynecology in the College of Medicine of the University of Nebraska, Omaha, and will remove to that city in the spring.

Decision Against Medical Society. Judge McKen of the Superior Court has rendered a decision against the Chicago Medical Society in its efforts to maintain in Grant Park a boulder placed there in memory of Dr. Charles Guthrie and his pioneer work on chloroform.

Personal.—Dr. Charles Adams has returned from a trip to Mexico. Dr. Nicholas Senn has been selected to deliver the oration on surgery at the International Medical Congress, Lisbon. Dr. Frank Billings is taking a yachting trip in the Caribbean. Dr. Willoughby Walling is visiting in New Orleans. Dr. S. Jakubowski has had his name changed by decree of court to S. Jackson.

Public Health Condition.—For the week ended February 24 decreases are shown in death rates of all diseases excepting typhoid fever, which remains the same as for the previous week. The deaths of the week numbered 594, equivalent to an annual death rate of 15.10 per 1,000. Pneumonia caused 108 deaths; consumption, 52; nephritis, 49; violence, including suicide, 44; heart diseases, 44; nervous diseases and cancer, each 31, and acute intestinal diseases, 30.

INDIANA.

Smallpox.—It is reported that 20 cases of smallpox have developed in Michigan City since February 25.

Damages Against Hospital.—Mrs. Lillie M. Grimes, Summitville, was awarded \$2,500 damages against the Marion Hospital Company, January 27, for injuries sustained June 16, 1904, by falling from a second-story window of the hospital.

Physician Acquitted.—Dr. William H. Dings, Mitchell, charged with having performed an illegal operation on Carrie Shaw, Sept. 8, 1894, from the effects of which she died, was acquitted in the Circuit Court, February 21.

Do Not Wish Notoriety.—At the regular meeting of the Fort Wayne Medical Society, the medical society of Allen County, February 20, a resolution was adopted that a scrap book be kept by the secretary of the society in which is to be preserved all articles appearing in the daily papers, in which the names of members of the society are mentioned in connection with cases.

Licenses Revoked.—The State Board of Medical Registration and examination has revoked the following licenses: "Dr." Louisa Wessell, Fort Wayne, and "Dr." Nelson D. Ross, Muncie. "Dr." George Snider, a "magnetic healer" of Richmond, has been ordered by the state board to discontinue the practice of medicine under penalty of being arrested and prosecuted for violation of the state law.

Pathologic and Bacteriologic Laboratory.—Indiana University, Bloomington, announces the opening of its new laboratory of pathology and bacteriology in which courses are offered in medical bacteriology, pathologic anatomy and pathologic physiology, and which offers gratuitous service to the physicians of the state in all lines of laboratory diagnosis falling within its province, such as examination of sputum, pus, genitourinary discharges, the tests for diphtheria, meningitis, malaria, typhoid fever, examination of autopsy material, uterine scrapings, etc.

January Disease and Death.—Bronchitis and tonsillitis were the most prevalent diseases; pneumonia stood fourth and scarlet fever fifth; in Allen County an epidemic of smallpox with 52 cases was reported. In all but 27 counties of the state typhoid fever was prevalent. The deaths of the month numbered 2,998, or 411 fewer than in January, 1905. The annual death rate for cities was 16.5 per 1,000, and for the country 11.5 per 1,000. Of the decedents 405 were less than one year of age and 794 had attained or exceeded the age of 65. Consumption caused 419 deaths; pneumonia, 415; violence, 122; cancer, 113; influenza, 45; cerebrospinal meningitis, 38; typhoid fever, 35, and diphtheria, 32.

Personal.—Dr. Allison Maxwell, Indianapolis, has resigned as emeritus professor of the practice of medicine in the Indiana Medical College, the school of medicine of Purdue University.

—Dr. T. Victor Keene, Indianapolis, was seriously burned while working in the State Laboratory, February 9. Dr. Thomas W. Moorhead has been elected president, and Dr. Myron A. Boor, secretary, of the Terre Haute Board of Health.

—Dr. George T. McCoy, Columbus, has been appointed a member of the State Board of Health, vice Dr. Charles M. Eisenweiss, Elkhart, resigned. Dr. Eisenweiss has been appointed postmaster of Elkhart. Dr. Martin Hassemiller, West Baden, has returned from Europe. Dr. B. Frank Chambers, Lyons, has been appointed surgeon for the Vincennes Division of the Vandalia Road. Dr. and Mrs. Ernest S. Baker, Lafayette, have left for California.

KANSAS.

Adds School for Nurses.—At the last meeting of the board of trustees of the University of Kansas it was decided to establish a school of training for nurses in the Kansas University Medical School, Rosedale.

School at Epileptic Hospital.—A school has recently been opened for the patients at the State Hospital for Epileptics, Parsons; 25 children are at present in attendance. Manual training will be given a prominent place in the school work.

Personal.—Dr. Alfred F. Yole, Leavenworth, has been appointed physician at the Federal penitentiary, vice Dr. F. Meigs

Thomas, resigned.—Dr. J. L. Everhardy, Leavenworth, has been appointed county health officer of Leavenworth County, and Dr. William R. Van Tyl, Leavenworth, county physician.—Dr. E. W. Reed, Holton, has been appointed physician of Jackson County, vice Dr. Joseph C. Shaw, term expired.—Dr. William C. Bower, Lebanon, has been appointed local surgeon for the Rock Island Railway System.

Hospital Notes.—Arrangements have practically been completed for the purchase of the Stewart Hospital, Hutchinson, by twelve physicians of the city, who will place the institution under the charge of the Dominican Sisters of Mercy. The officers of the institution are: Dr. Clemens Klippel, president; Dr. James E. Stewart, vice-president; Dr. J. E. Foltz, secretary, and Dr. Richard A. Stewart, treasurer.—At the annual meeting of the board of directors of the Wichita Hospital it was announced that the hospital is practically self-supporting, the deficit for 1905 having been only \$77.27.—The directors of the Sabetha Hospital Company have decided to increase the capital stock to \$50,000 in order to build a large brick addition to the present building, which is overcrowded.—The Sisters of Charity expect to build a hospital in Leavenworth at an expense of not less than \$50,000.

LOUISIANA.

One Case of Yellow Fever.—On January 28 one case of yellow fever was reported from Kenner, Jefferson Parish, by Dr. Gustave M. Corput of the U. S. Public Health and Marine-Hospital Service.

Sanitarium Fire.—The Fenwick Sanitarium, Abbeville, was burned to the ground February 6, but all the patients were removed in safety. The loss is estimated at \$40,000, three-fourths of which is covered by insurance. The institution will be rebuilt.

Lepers' Home Purchased.—After long negotiations the Indian Camp property in Iberville Parish has been purchased by the state for the lepers' home. The land comprises about 358 acres, and on this four twelve-room cottages will be erected, each containing ten bedrooms.

The New State Board of Health.—The new State Board of Health reorganized January 8 with the following officers and members: President, Dr. Clifford H. Irion, New Orleans; vice-president, Dr. W. Glendower Owen, White Castle; secretary, W. S. Ingram, New Orleans, and members, Drs. George W. Gaines, Tallulah; Allen J. Perkins, Lake Charles; T. Edgar Schumpert, Shreveport; James M. Batchelor, New Orleans, and William G. Armstrong, New Orleans. The central office of the board will continue to be at 204 Carondelet Street, New Orleans.

Personal.—Dr. Clifford H. Irion, Benton, recently appointed president of the State Board of Health, has moved to New Orleans, and Dr. R. A. Gullage of Gilliam has purchased Dr. Irion's practice.—Dr. J. Wofford Sanders has resigned as a member of the board of health of New Iberia, and Dr. William J. Emmer has been appointed his successor.—Dr. Charles M. Menville, Houma, has been appointed coroner of Terrebonne Parish, vice Dr. Clairborne A. Duval, deceased.—At the annual meeting of the board of administrators of the Charity Hospital, New Orleans, February 5, all the officers of the board and of the hospital without exception were re-elected.

MARYLAND.

Building Fund for Hospital.—The directors of the Union Hospital of Cecil County are making efforts to raise \$5,000 additional and expect to commence building during the summer at Elkton. Committees have been appointed on plans and site.

Baltimore.

Deaths.—There were 51 deaths from pneumonia and 34 from consumption for the week ended February 24.

Anniversary Exercises.—At the John Hopkins thirtieth anniversary exercises, held February 22, Prof. Lewellys F. Barker, Dr. Osler's successor, delivered an address on "The Science of Medicine and Medical Practice." A marble bust of Dr. William Osler was presented to the university by Mr. Daniel C. Gilman, ex-president, on behalf of the admirers of Dr. Osler. It will be placed in McCoy Hall.

Personal.—Dr. George C. Weegar has gone to Cuba.—Dr. John Williamson Palmer, the distinguished poet and author of "Stonewall Jackson's Way," is critically ill.—Drs. James S. Fenton, William S. Love, James D. Iglohart, C. Milton Linthicum, C. Frank Jones, Elias Baldwin, Frederick Cauthers, Patrick F. Martin and Thomas S. Suller have been appointed coroners for Baltimore.

MASSACHUSETTS.

Must Report Tuberculosis.—Boston physicians have been notified by special circulars that they must report all cases of tuberculosis coming under their observation. It is thought that not more than one-half such cases have been reported in the past.

Westfield Vital Statistics.—The board of health of Westfield reports 203 deaths in 1905, a rate of 14.91 per 1,000. Of these 20 were from pneumonia, 25 from tuberculosis, and 29 from heart disease. There were in the town, during the year, 94 contagious cases: typhoid fever, 49; scarlet fever, 24; diphtheria, 12; measles, 8, and cerebrospinal meningitis, 1.

Appointment Confirmed.—Dr. Walter R. Brinkerhoff has received official notice of his appointment as director of the United States Government Leprosy Research Hospital, to be located in the leper settlement, Molokai, Hawaii. He is to work under Surgeon-General Wyman and will leave Boston soon to take charge of the erection of the necessary buildings.

Allow Expert Fees.—District Attorney John B. Moran has failed to make the Massachusetts committee on public service believe that the medical examiners in Suffolk County shall not be allowed expert fees for testimony given by them in cases arising out of and connected with autopsies or inquests performed or conducted by them in their official capacity as medical examiners.

Use Much Water.—In a legislative hearing in regard to enlarging the water supply of Springfield it was developed that the city now uses 150 gallons per day per capita, while other cities and towns use much less: Chelsea, 113; Quincy, 101; Malden, 60; Pittsfield, 100; Taunton, 46; Leominster, 60; Natick, 40; Haverhill, 60; Newton, 55; Brookline, 90; New Bedford, 76, and Brockton, 35.

Tuberculosis Exhibit.—The state tuberculosis exhibit, the outgrowth of the recent exhibition in Horticultural Hall, has been completed and is to be on exhibition for one week, beginning February 28, at the Franklin school house, Boston, and then one week at the North Bennet Street industrial school. Thence it will go successively to Lynn, Lowell, Worcester, Springfield, North Adams and Fall River. The cost of maintaining it a week is \$100 beside hall rent.

MISSOURI.

Hospitals Opened.—St. Luke's Hospital, Kansas City, was opened to receive patients February 19. It is hoped within two years to begin the erection of a hospital to cost \$250,000.—The new St. John's Hospital, Springfield, was opened to the public February 22.

Memorial Meeting.—Memorial services for the late Dr. Elisha Hall Gregory were held February 18 in the Y. M. C. A. building, St. Louis. Dr. George Homan, president of the St. Louis Medical Society of Missouri, presided, and the eighteen past presidents of the society were named as honorary pallbearers. The members of the society attended the funeral services in a body.

Personal.—Dr. John H. Duncan, St. Louis, has gone to Europe.—Dr. and Mrs. C. B. Hewitt, Kansas City, left for Cuba, February 14.—Dr. J. H. Simons, St. Louis, is confined to his house with an infected wound of the foot.—Dr. C. R. Woodson, St. Joseph, has been decided not guilty of contempt of court "since he disclaims any purpose of intention of contempt."—Dr. William F. Meyer, St. Louis, has been exonerated, as the coroner has decided that in killing his brother Dr. Meyer acted in self-defense.

NEW YORK.

Osteopaths Fined.—C. E. Rumsey, Watkin, and O. C. Clock, Elmira, were each fined \$50 for illegal practice of medicine.

Fire in Physician's House.—Fire in the residence of Dr. Andrew J. Dick, Watertown, caused damage of about \$600, fully covered by insurance.

Insane Transferred.—One hundred and twenty-five patients have been transferred from the Hudson River State Hospital, Poughkeepsie, to the St. Lawrence State Hospital, Ogdensburg.

Examination for Medical Inspectors.—A civil-service examination was held in Syracuse, February 3, for the position of medical inspector of public schools. There were twenty applicants for the ten positions.

Sentenced to Prison.—Adam Blackburne, a barber of Fairport, charged with practicing medicine without having been legally registered, pleaded guilty and was sentenced to six months in the penitentiary.

Hospital Donations.—The first day of the annual donation to the Rochester City Hospital netted nearly \$11,000 for the institution.—By the will of Albert G. Pitkin, New York, \$5,000 is bequeathed to the Hospital Association of the City of Schenectady.—Friends of the City Hospital, Watertown, have subscribed \$3,200 toward the payment of the debt of \$13,000 on the institution.

Associated Physicians Meet.—The Associated Physicians of Long Island held their eight annual meeting in Brooklyn, January 27, at which the following officers were elected: Dr. Elias H. Bartley, Brooklyn, president; Drs. J. Ensor Hutcheson, Rockville Center; H. Beekman Delatour, Brooklyn, and Arthur H. Terry, Patchogue, vice-presidents; Dr. James C. Hancock, Brooklyn, secretary, and Dr. Charles B. Bacon, Brooklyn, treasurer.

Personal.—Dr. Frederick H. Millener, Buffalo, has been appointed surgeon-in-charge of the nose, throat and ear department of the German Hospital Dispensary.—Dr. Sydney F. Rogers, Cohoes, was injured by being thrown from his buggy in a collision, February 4.—Dr. James C. Sharkey has been appointed health officer of Rensselaer, vice Dr. William L. Allen, retired.—Dr. James E. Medden, Seneca Falls, recently fell while alighting from his buggy and sustained a Colles' fracture.—Dr. George F. Mills has been appointed health commissioner of Oneida.—Dr. George E. Swift has been chosen as health officer of Hudson, vice Dr. Henry W. Johnson, retired.—Dr. John Arnhild has assumed the duties of mayor of Cohoes.—Dr. John J. English has resigned as police surgeon of Troy.—Dr. La Salle Archambault, Cohoes, has returned after two years in Europe.—Dr. Frederick W. Parsons, Poughkeepsie, has been appointed second assistant physician of the Hudson River State Hospital, Poughkeepsie, vice Dr. Charles H. Langdon, deceased.—Dr. Clarence E. Caruth has been appointed city physician of Cohoes, vice Dr. Edward M. Bell.—Dr. Martin Cavana, Oneida, has been reappointed surgeon for the New York, Ontario & Western Railroad.—Dr. Edgar H. Douglass, Little Falls, has been appointed surgeon for the Little Falls and Frankfort division of the New York Central Railroad.—Dr. Amos P. Dodge, Oneida, has been reappointed local surgeon of the New York Central Railroad and of the West Shore Railroad.

New York City.

Charter for Postgraduate School.—A limited charter for three years has been granted to the Brooklyn Postgraduate Medical School by the State Board of Regents.

Middleton-Goldsmith Lecture.—The Middleton-Goldsmith lecture of the New York Pathologic Society was given February 23 by Dr. Ludvig Hektoen, Chicago, on "Phagocytosis."

Harvey Society Lecture.—The eleventh lecture in the Harvey Society course will be delivered at the New York Academy of Medicine by Prof. J. Clarence Webster, Chicago, March 3, on "Modern Views Regarding Placentation."

Sued for Alleged Neglect.—Suit has been commenced against Dr. Herman J. Boldt for damages said to have been caused by the defendant allowing "a towel" to remain in the body of the plaintiff for a long period of time after the performance of a laparotomy. The plaintiff claims \$25,000 damages. Dr. Boldt says there is no justification for the suit.

Arraigned and Exonerated.—Dr. John A. Burke, who was arrested January 8 on the charge of complicity in an illegal operation on Mrs. Lillian Kropf, was discharged January 29, fully exonerated.—Dr. Carl F. B. Puchs, Brooklyn, charged with having performed a criminal operation on Mrs. Anna Hoffmann, Ridgewood, was discharged from custody January 29.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended February 17, 1,674 cases of measles, with 37 deaths; 371 cases of diphtheria, with 62 deaths; 328 cases of tuberculosis, with 176 deaths; 198 cases of scarlet fever, with 11 deaths; 100 cases of variella, with 1 death; 30 cases of cerebrospinal meningitis, with 21 deaths; 30 cases of typhoid fever, with 10 deaths, and 1 case of smallpox; a total of 2,732 cases, with 318 deaths.

Tuberculosis Exhibit Opened.—Between 2,000 and 3,000 persons visited the traveling tuberculosis exhibit of the committee on the prevention of tuberculosis of the Charity Organization Society, which was opened to the public in the Educational Alliance building on February 20. It will remain open until March 10. Dr. Alfred Meyer delivered a lecture. Stereoscopic views were shown illustrating how the roofs of tenement houses could be used as sanatoria.

Brooklyn Wants a Health Commissioner.—The Kings County Medical Society has announced itself as in favor of having a health commissioner instead of an assistant sanitary superintendent. The society contends that the health department can not be administered with satisfaction either to the medical profession or the public because of lack of authority and direct responsibility. An appeal has been made to President Coker requesting him to have a bill proposed providing for the appointment of a health commissioner for this borough.

Interne Anesthetists Organized.—The interne anesthetists of the various Brooklyn hospitals have organized a conference to meet at the various hospitals from time to time and listen to papers, reports of cases, etc. The first meeting was held at Long Island College Hospital, December 19, on invitation of Dr. Adolph E. Erdman. After an informal social half-hour Dr. James T. Gwathney, Manhattan, demonstrated the use of his new vapor inhaler. The January meeting was held at the Bushwick Hospital on invitation of the consulting anesthetist, Dr. Woolsey.

Gifts to Hospitals.—Isaac Guggenheim has given \$250,000 to the Sydenham Hospital for the erection of a new building, conditioned on the raising of a sufficient endowment by the hospital directors for the maintenance of the institution.—By the will of the late Margaret H. Jones, St. Luke's Hospital, Presbyterian Hospital and the Postgraduate Hospital will each receive at least \$125,000.—Nearly \$20,000 has been paid into the treasury of the Beth Israel Hospital as a nucleus of the fund for the annual Purim ball, to be held March 14 for the benefit of the poor of the East Side.

Bronx Medical Society.—This society was organized two months ago by about forty physicians of Bronx borough. Dr. Alfred P. Brugman was made president of the society. One of the first subjects for discussion was an amendment to the vaccination bill, now before the legislature, releasing from compulsory vaccination the children of parents who have scruples against vaccination. The society adopted a resolution protesting against the passage of any measure which would allow unvaccinated children in the public school and directed that the members of the legislature from the Bronx borough should be informed of this action.

Pasteurized Milk for City's Wards.—All milk and cream *bought by the charities department is now pasteurized. The department purchases daily about 3,000 quarts of milk for the 6,000 inmates in the city's charitable institutions, and all the milk is pasteurized before its delivery by the contractor. The contract requires that all the milk shall be raised to a temperature of not less than 155 degrees nor more than 167 degrees F. and shall immediately be cooled to a temperature of 45 degrees F. or less. The process is so simple that there is scarcely an appreciable difference in the cost of the milk. The beneficial effects have been chiefly noted in the improved keeping qualities of the institutional supply.

NORTH CAROLINA.

Personal.—Dr. Charles L. Minor, Asheville, was painfully injured in an automobile accident recently.

Hospital Notes.—Pittman Hospital, Tarboro, is being enlarged.—The physicians of Raleigh are actively working for the establishment of a new general hospital in that city.—Mission Hospital, Asheville, has added a new wing, which was formally opened last month.

Sanatorium Company Chartered.—The Crowell Sanatorium Company opened at Charlotte, January 1. The new company has absorbed the Crowell Sanatorium, Charlotte. The officers of the new company are: Dr. S. M. Crowell, president; Dr. I. W. Faison, vice-president; Dr. W. M. Strong, secretary-treasurer, and resident physician.

Preparation for State Meeting.—The Mecklenburg County Society has taken action regarding arrangements for the annual meeting of the Medical Society of the State of North Carolina, in Charlotte, May 29 to 31. Dr. Robert L. Gibbon was chosen chairman of the committee of arrangements, and Drs. R. J. Brevard, John R. Irwin, W. O. Nesbet and E. P. Russell make up the remainder of the committee. The president of the society, Dr. E. C. Register, was also made a member.

PENNSYLVANIA.

Bequest to College.—By the will of the late John Porterfield, Allegheny, \$50,000 is ordered to be paid to the Medical Department of the Western Pennsylvania University, Pittsburg, on the death of the testator's sister.

Entertained Takaki. The Allegheny County Medical Society entertained Baron Kaichiro Takaki, surgeon general of the

Japanese imperial navy, February 14. A dinner was given at the Hotel Schenley, after which an address was delivered by Baron Takaki, followed by a smoker-reception at the German Club.

Railway Surgeons Meet.—The annual meeting of the Pittsburgh & Lake Erie Railway Surgeons' Association was held at Pittsburgh, February 15. Dr. John D. Milligan, Pittsburgh, was elected president; Dr. Edward M. Hand, Conopopolis, was re-elected secretary, and Drs. Loyal W. Wilson, New Castle, and George W. Gallagher, New Haven, were elected vice-presidents.

Hospital Notes.—St. John's General Hospital, Allegheny, is to be enlarged so that it will accommodate at least 60 more patients, at a cost of more than \$25,000. Forty physicians of Harrisburg have formulated plans for the institution of a private hospital in Harrisburg. Dr. C. A. Rahter was elected chairman, and Dr. C. M. Rickert, secretary, of the organization.

Damages for Physician's Death.—The United States Admiralty Court handed down a verdict of \$25,000 in favor of the widow and children of Dr. J. M. B. Ward of Marcus Hook, against the Steamship Company of Copenhagen. Dr. Ward was killed by falling down the hold of the steamer *Eurinia*, Jan. 21, 1903, while in the discharge of his duties as quarantine physician.

Monongahela Valley Medical Society.—At a meeting held in Monessen, January 25, this society was organized. The membership includes physicians from Washington, Fayette and Westmoreland counties. The following officers were elected: Dr. John W. Gordon, Bellevue, president; Dr. Harry J. Reppman, Charleroi, vice-president; Dr. Joseph W. Hunter, Monessen, secretary; Dr. J. C. Enos, Charleroi, corresponding secretary; Dr. Howard R. Day, Monessen, treasurer, and Drs. George E. Nickels, Bellevue; McKay, Charleroi, and Arthur R. Wilson, Monessen, censors.

Personal.—Dr. George B. Kunkel has been appointed surgeon of the Philadelphia & Reading Railway in Harrisburg.

—Dr. H. E. Zerner has resigned as alderman of New Castle.

—Dr. Isadore J. Weida, Etnaus, has been elected president of the board of health, vice Dr. Martin B. Backenstoe, resigned.

—Dr. Ralph W. Montelius, Mount Carmel, has been appointed surgeon for the Philadelphia & Reading Railway between Port Clinton and Williamsport.

—Dr. J. Marion Vastine, Catawissa, has been appointed division surgeon for the Philadelphia & Reading Railroad.

—Dr. Theodore B. Lashells, Meadville, fell January 31, fracturing his right hip.

—Dr. Charles W. Everhart, Roversford, who has been a patient at the Phoenixville Hospital, became violently insane, January 10, and was removed to the State Hospital for the Insane, Norristown.

—Dr. Charles D. Schaefer, Allentown, has been unanimously elected acting mayor of that city.

—Dr. Jacob Stiekel, Williamsport, was recently operated on for a tumor of the left breast.

—Dr. Lauran C. Thomas, Latrobe, has been appointed local surgeon for the Pennsylvania Railroad.

Philadelphia.

Gift to Hospital.—At the annual meeting of the Methodist Episcopal Hospital, February 9, it was announced that \$2,000 had been subscribed for a new ward.

Diphtheria Closes School.—On account of the discovery of two cases of diphtheria in the Meredith school, February 23, the school was ordered closed and fumigated.

Illegal Practitioner Sentenced.—A woman who advertised as "Dr. Roberts, female specialist," was tried in the Criminal Court, January 30, charged with abortion, was found guilty and sentenced to three years in the Eastern penitentiary.

Medical Inspection.—The reports, made February 23, of medical inspections during January, show that in 315 public schools 6,451 visits were made. Treatment was recommended in 4,483 cases, and 1,561 children were excluded from attendance. Of these 691 were boys and 870 girls. The number of pupils readmitted was 802. Vaccinations were made in 277 instances.

Alumni at Banquet.—The dinner given by the alumni of the University of Pennsylvania Medical School, February 21, was attended by more than 260 persons. The toastmaster was Dr. George E. de Schweinitz. Among the speakers were Provost Harrison on "The University of Pennsylvania"; Dr. George A. Piersol, "The Medical Faculty of the University"; Dr. W. W. Keen, "Sister Medical Schools"; Dr. George Guthrie, "Pennsylvania Alumni"; Dr. John A. Witherspoon, "The Alumni from Afar"; Dr. Daniel M. Hoyt, "The Junior Alumni"; and Dr. Selvester J. Dechan.

Surgeon-General Takaki in Philadelphia. Surgeon-General Kanekiro Takaki of the Japanese army and navy spent the

week of February 19 to 24 in this city. He received the degree of bachelor of science at the "University Day" exercises, February 22. February 23 he addressed the students of the university on "Sanitation in the Army and Navy", and on February 24 he addressed the students of Jefferson Medical College in the amphitheater of the college on "The Medical College Conduct of the Russo-Japanese War", and stated that the Japanese had received their surgery from the teaching of Dr. Gross.

Prevalence of Measles.—The epidemic of measles shows no sign of abatement, according to reports of the bureau of health. Since January 1 there have been 4,921 cases reported, but large as the number is, it does not include all sufferers, for in many instances medical advice is not sought, and in such cases returns are not made to the health authorities. In the six days which ended at noon February 23, there were 649 cases reported, and it is believed that the number for the week will exceed that of any week since the disease became prevalent. In the first week of the present year 353 cases of measles were reported, and the disease has steadily progressed ever since.

Much Typhoid.—The prevalence of typhoid fever has reached the highest mark in about three years. Dr. A. C. Abbott emphasizes the importance of filtration and has compiled the following figures: In the Queen Lane district with unfiltered water there have been during the week 63 cases of typhoid, among a population of 293,230 people, or 21 cases to every 1,000 inhabitants. In the Wentz farm reservoir district, which is supplied with unfiltered Delaware water, there have been 87 cases among 176,712 people, or 49 cases for every 100,000 people. In the filtered water district of West Philadelphia, with 42,000 population, there was not one case of typhoid fever. There have been but three cases since January 1. In the Twenty-first and Twenty-second wards, which are supplied with filtered water, and which include 113,000 people, there were but seven cases. The records of the health bureau show that there are 2,300 cases of typhoid under treatment in the city.

Personal.—Drs. Charles Browne and E. J. Porteous left February 23 for an extended tour of the Pacific Coast.—Dr. Rebecca Fleisher, who has been ill for many weeks, has returned to her home in Philadelphia.—Dr. and Mrs. L. Webster Fox have returned after a month spent in Port Antonio, Jamaica.—D. Richard H. Harte, surgeon to the Pennsylvania Hospital, has been elected a member of the city council.—Dr. E. G. Whinna, who has been in falling health, has left the city to recuperate.—Dr. Arthur R. Cobb, while in a state of despondency, jumped from the second-story window of a cottage in Cape May, and sustained general contusions and fractures of both arms. He is convalescing in the Hahnemann Hospital.—Dr. Joseph P. Tunis entertained the Biological Club at dinner at his residence, February 23.—Dr. Robert Abbe, New York City, will address the W. W. Keen Surgical Society of Jefferson Medical College in the amphitheater, March 17, at 8 o'clock, and will be given a reception at the Bellevue-Stratford after the address.

GENERAL.

Cholera in Manila.—Dr. Heiser, chief quarantine officer, reports that the cholera situation in Manila remains about the same. A few sporadic cases have occurred in the city, but in almost every instance the infection could be traced to the outside. He states that cholera has practically described an entire circle of a radius of 25 miles around the city of Manila. In view of the very few cases of cholera in Manila and their sporadic character, it was deemed advisable still further to modify the outgoing interisland quarantine which was placed on vessels.

Health Report of the Isthmus for January.—Colonel Gorgas reports that the health of the Isthmus continues excellent. In January there were 22,000 employes on the rolls and the daily sick list was about 503; this gives an average sick rate of 22 per mille. Such loss from sickness, Colonel Gorgas states, compares very favorably with that of any body of men working anywhere. The daily sick rate is an accurate measure of the loss to the commission from illness. It does not necessarily mean a low death rate. During January the number of deaths from pneumonia was large. Among the employes there were 74 deaths, and of those 26 were from pneumonia. Most of these were among negroes. Only one American died from this disease. The report states that surprise has been expressed that there should still be breeding places of mosquitoes on the Isthmus, but calls attention to the fact that when the Americans left Havana after a most successful yellow-fever cam-

paign, the last inspection showed something like 300 breeding places in that city. Mosquito work on the Isthmus has reduced the number of such places to the minimum. There have been no new cases of yellow fever since the last report.

FOREIGN.

Little Plague in Japan.—Acting Assistant Surgeon Fowler of the United States Public Health and Marine-Hospital Service reports that after a cessation of thirteen days a case of plague occurred in Kobe.

Frontier Practice.—A number of physicians residing on either side of the boundary between France and Belgium met recently at Paris to draw up a satisfactory code of ethics for their guidance in frontier practice.

Prizes for Milk Supply and Housing of the Lower Classes.—An international exposition of hygiene is to open at Milan in May and to continue through the summer. To celebrate the occasion the king of Italy has offered a prize of \$1,000 for the best well-tested arrangement for supplying cities with pure milk. A second prize of \$2,000 is also offered for the best type of dwelling house for the masses adapted to the climate of southern Italy.

Proposed Changes in Examinations at University of Edinburgh.—Changes in the medical course at the University of Edinburgh are proposed, to enable students to appear for examination in the earlier subjects of the curriculum at an earlier period than has been the case. This is to give more time for the final subjects. The *Lancet* states that it would still further help if the university court had applied for powers to prevent, when it was thought desirable, students attending classes of an advanced division when they had failed in the subjects of an earlier division. Meanwhile the university has no such power, the result being that the work of classes is sometimes hindered by a number of students attending who are not in a position to benefit by the class and who act as a drag on the others.

Von Noorden in Vienna.—As already mentioned, Carl H. von Noorden, at present in Frankfurt, has accepted the summons to the chair of internal medicine left vacant by the death of Nothnagel at Vienna. The Vienna authorities agreed to all his terms, promising the completion of the new model clinic in two years and the erection of a new laboratory for him, with extensive remodeling of the present clinic at once. He is to bring his assistant with him, and the latter is to have a professorship of medical chemistry created for him. Von Noorden has never been a clinical teacher, and it will be a great change for the specialist in the pathology of the metabolism to attempt to fill the chair of Nothnagel and Skoda, distinguished for their universality and skill as teachers. A Vienna correspondent of the *Deutsche med. Wochts.* refers casually to the danger of von Noorden's making the clinic one for metabolic affections exclusively, but the editors comment that von Noorden's record should banish this fear. He made many friends in this country during his recent visit here to lecture. One of his addresses then on some of the problems of metabolism was published in *THE JOURNAL* at the time, Oct. 28, 1905, as our readers will remember. He is comparatively a young man, not quite 48.

Announcements by von Behring in Regard to "Immune Milk Supply" in Prevention of Tuberculosis.—On February 8 Professor von Behring lectured at Berlin on this topic before the German Agricultural Council. He announced that he had lately perfected an inexpensive method for producing and keeping the immunizing properties of the tubercle bacilli for injection while at the same time destroying the vitality of the tubercle bacilli. He calls the fluid thus obtained "tuberculase" and expressed hopes that it was destined to prove an effective aid in the stamping out of tuberculosis among men and animals. He added that he had not been experimenting with tuberculous cattle in a condition even remotely approximating that of a consumptive human being, and consequently, he continued, "I have no scientific basis for the assumption that tuberculase may prove an effective remedy for human pulmonary tuberculosis. I did not speak at Paris of a remedy for consumption in the sense of a cure for already established tuberculous destruction of lung tissue. I spoke only of a remedy to prevent consumption in young persons by acting on an already existing tuberculous focus in such a way that its self-healing may proceed with the natural healing powers of the organism, undisturbed by renewed tuberculous infection." He aims to render children immune to tuberculosis by feeding them on milk from cows immunized with tuberculase. The children will then grow up refractory to tuberculous infection.

Pharmacology

Indorsements of Campaign Against Nostrums.

Dr. C. W. Dulles, Philadelphia, writes:

"As one who has followed the career of *THE JOURNAL* since its birth, I wish to express the gratification with which I have seen it attain a degree of scientific excellence that makes it the equal (*me judio*) of any medical periodical in the world. At the same time, I may express the pleasure it gives me to find it fully enlisted in the cause of intelligence and decency in the application of medicinal agents to the treatment of disease and warring against the credulity of the medical profession and the unscrupulousness of the manufacturers of many proprietary medicines. Having for years, in private and in public, borne testimony against these two disgraces of our time, it is most encouraging to see so strong a champion of the good cause enter the lists. May your efforts be as successful as your object is laudable."

Dr. Victor H. Dye, Sistersville, W. Va., writes:

"At this time I take pleasure in heartily indorsing everything that *THE JOURNAL* has done and is doing in the crusade against 'patent' and proprietary medicine vendors. It is exactly portraying my sentiments regarding that curse of the American people."

Dr. W. C. Herman, Cincinnati, writes:

"I take great pleasure in sending you my congratulations for the great work *THE JOURNAL* is doing for the physician and for the laity as well in its exposure of the nostrum evil. This work comes a little bit late, it is true, but everything comes to him who waits' good and bad."

Dr. Theodore Zbinden, Toledo, Ohio, writes:

"I wish to express my approval of all the undertakings of the American Medical Association, and wish to say that I am especially pleased with the work of the Council on Pharmacy and Chemistry. I am looking into the matter of patent-medicine advertisements published in some religious journals and hope to accomplish something in that way. Be assured of my hearty co-operation with the officials of the American Medical Association in all their good work."

At the regular meeting of the Muscogee County (Ga.) Medical Association, February 7, the society unanimously indorsed the resolutions adopted by the Suffolk District Section of the Massachusetts Medical Society, approving the action of the American Medical Association in establishing the Council on Pharmacy and Chemistry, and commending the educational campaign now being conducted by *Collier's Weekly* and the *Ladies' Home Journal* in exposing the business methods of the Proprietary Association of America.

Similar resolutions were adopted by the Androscoggin County (Maine) Medical Association, the Logan County (Ohio) Medical Society, the Delaware County (Ohio) Medical Society, the Utica (N. Y.) Medical Library Association, the Champaign County (Ill.) Medical Society, the Fayette County (Ky.) Medical Society, the Lenawee County (Mich.) Medical Society, the Chattanooga and Hamilton County (Tenn.) Medical Society and the Calhoun County (Ala.) Medical Society. Each member of the last named society was also requested to write a personal letter of commendation to the editors of *THE JOURNAL* of the American Medical Association, the *Ladies' Home Journal* and *Collier's Weekly*.

A Physician's Experience with Acetanilid.

The physicians of Racine, Wis., recently gave a banquet for the members of a medical society in an adjoining town. The afternoon preceding the banquet one of the visiting physicians took several powders of acetanilid and caffeine, and immediately before the banquet—about 9 p. m.—he took one or two more. In all he took about 18 grains of acetanilid. As the banquet progressed he gradually became cyanotic, but seemed normal otherwise until collapse occurred. The heart action was very weak, and there were nausea, vomiting, diarrhea, and intense cyanosis. He was at once put to bed in the hotel in which the banquet was held, and several physicians worked over him all night. Powerful stimulants were applied, but he was not con-

sidered out of danger till the next morning; and even then there was still some cyanosis. He was not able to go home till after thirty-six hours had elapsed.

Poisoning from Electric Headache Powders: Recovery.

Dr. A. P. Merrill, Pittsfield, Mass., reports January 23, that he was called to see a woman about 27 years old. She was suffering with considerable pain in the stomach and said she "felt cold and numb all over," and was listless and could hardly be roused to answer questions. She had had a bad

irregular, and for over an hour the radial pulse could not be felt. He decided that she was suffering from acetanilid poisoning and treated her accordingly, giving stimulants and applying external heat. The woman was ill for a number of days, and for forty-eight hours she could hardly keep awake. During that time the extremities were cold and more or less numb. Her digestion was much upset, and Dr. Merrill states that she reached normal only after three weeks or more. The powders taken by this patient were labeled "Electric Headache Powders" and were bought at a local drug store.

THE SLAUGHTER OF THE INNOCENTS.

Kopp's Baby's Friend.

In THE JOURNAL, Nov. 25, 1905, page 1678, there appeared a letter from an Onahia physician reporting the death of a child following administration of four drops of Kopp's Baby's Friend.

In the same issue we published the report of an analysis of this preparation. According to this analysis, Kopp's Baby's Friend contains in 100 c.c., 0.0719 gm. morphin sulphate; approximately one-third of a grain in one fluid ounce.

On January 6, 1906, page 54, we noted a report of the death, in Baltimore, of a child aged three and one-half months following administration of this preparation. As will be remembered, in reporting this case we quoted from a published statement of the state's attorney, in which he emphasized the "urgent need of a law prohibiting the sale of any patent or proprietary medicine containing any deadly drug unless the same is labeled 'Poison.'"

On Feb. 10, 1906, page 447, we printed a letter from the physician who reported the first-mentioned case, notifying us of a case of poisoning from the use of this "remedy."

We have now to record two other deaths which, it is alleged, have followed the administration of Kopp's Baby's Friend. In Utica, N. Y., twin children, a boy and a girl, aged five weeks, were given the preparation in

the evening; the boy is said to have been given four drops and the girl two. In the morning each were given another dose. Both children died that day, the boy at 2:30, the girl at 7:45 p. m.

"The said Adam and Eve Gnad, otherwise known as Zarlah, died on the 25th day of January, 1906; the boy died at 2:30 p. m. and the girl died at 7:45 p. m. at No. 25 Kossuth

headache for three days and on that evening had taken a headache powder, and as she felt worse after it she took another in twenty minutes, as the directions were to repeat if necessary. In about fifteen minutes after taking the second powder she felt numb, cold, very tired and sleepy, and had difficulty in speaking. There was absolutely no feeling in the extremities for over two hours. Dr. Merrill says that when he saw her, about thirty-five minutes after she had taken the second powder, she had considerable pain in the stomach, the pupils were markedly dilated, the heart action was very weak and

Avenue, in the City of Utica, County of Oneida, N. Y., of morphin poisoning. The evidence shows that Stanislaus Gnad, the father of the infants, had administered to them a dose of a mixture, which is known as 'Kopp's Baby's Friend,' on the night of January 24, 1906, and that the infants (whose age was one month and one day) died on the following day. Now after investigating the circumstances attending such deaths and obtaining the report of Drs. James C. Hunt and H. F. Preston, who made an autopsy on the bodies of the deceased infants and also the report of Drs. Nelson and Smith, chemists, who made an examination of the

stomachs and stomachs' contents of the dead infants, and also an examination of a portion of the mixture above mentioned, showing that it contained morphin, I find and decide that the said Adam and Eve Gnad, otherwise called Zarlah, died from an overdose of 'Kopp's Baby's Friend' which was administered by their father, but without criminal intent."

Thus without any particular effort on our part there has come to our attention within three months evidence of four deaths and one case of poisoning from this "soothing" medicine for infants. The question is, how many cases have occurred to which our attention has not been called, or which have not been reported? Is it possible that we have accidentally heard of all of all such cases? Is it more likely that there are hundreds that are never even reported to

the corner? Of course, it would be wrong to check this kind of business by legislation; vested interests are at stake, especially vested interests of newspapers. Kopp's Baby's Friend is only a sample; it is no worse than hundreds of others that are allowed to be sold for the aggrandizement of the few, but to the injury and death of the many.

Poisoning from Mrs. Winslow's Soothing Syrup.

Dr. G. M. Cummins, Hamilton, Ohio, reports a case of poisoning from Mrs. Winslow's Soothing Syrup, which occurred in his practice.

Oct. 24, 1905, he was called to see a male twin child, aged 3½ months, suffering from cholera infantum. He ordered a restricted diet and prescribed as follows:

R. Bismuth subnitratissgr. xii	75
Pepsini (pure)gr. xl	60
Aquæ q. s. ad.ssss	45
Sig.: Shake and give 1 teaspoonful every hour.

© ROBERT KOPP, Manager and Manufacturing Chemist

Utica, N. Y., Dec. 21, 1905.

City Clerk,
Knoxville, Tenn.

Dear Sir:

Would you for a compensation furnish me with a monthly report of the births occurring in your city? What I desire is the fathers' names and addresses. In case of illegitimates, the mothers'. I have made arrangements with the City Clerk in many cities for the furnishing of this report and would like very much to have that of your city.

Kindly let me hear from you and oblige

Yours very truly,

MRS. J. A. KOPP.

CCD

[It is purely a coincidence that we are able to reproduce the above letter at such an appropriate time. It was sent by Dr. Cochrane, secretary of the Board of Health of Knoxville, and was received by us February 24, in the same mail that brought a certified copy of the coroner's verdict on the Utica poisoning cases.]

At 12 o'clock that night he was called and told the baby could not be aroused, that it had been sleeping for an hour or more and had almost stopped breathing. A neighbor had suggested giving the child a dose of Mrs. Winslow's Soothing Syrup and it had been given two doses of one-half teaspoonful each, one-half hour apart. On examination Dr. Cummins found the pupils contracted to the size of a pinhead, pulse very slow and respirations four a minute. He diagnosed opium poisoning. Dr. Cook was called in consultation, and after four hours' work they succeeded in bringing the patient around all right. Dr. Cummins states that he has no doubt that this was a case of opium poisoning from the morphin contained in the soothing syrup.

Chamberlain's Colic Remedy Satisfactory to a Morphin Habitue.

A correspondent sends us a newspaper containing the following item:

Judge Smith sentenced Miss Ella Clark of the city (Mason City), to Mt. Pleasant asylum to-day (Jan. 23, 1906). She was proven to be addicted to the use of morphin to the extent that her health has been undermined and she is now almost a physical wreck and is confined to her bed. In her desire for the drug she brought large quantities of Chamberlain's colic remedy, which it is said she has been using for years.

Problin.

New York, Feb. 21, 1906.

To the Editor:—The article on "The Pharmacopœia and the Physician" in THE JOURNAL, February 10, contains, under the caption, "Laxative Sweet Substances," a reference to and a footnote on problin. We beg leave to state that problin is not a "laxative sweet substance"; the phenolphthalein it contains is merely an adjuvant.

The note makes no mention of the fact that problin is primarily a biliary disinfectant, the salicylic acid it contains being excreted by the epithelia of the biliary passages. Among many others, Dr. Kuhn (*Zeitschr. f. kl. Med.*, vol. lxxiii) reports in detail extensive experiments which show that salicylic acid is the best biliary disinfectant.

The assertion that salicylic acid and acid sodium oleate are the most powerful chologogues is perfectly "in accord with the generally accepted opinion of therapeutists." Thus Professor Stiller (*Wien. med. Woch.*, 1, 1905) writes that according to Mandelstamm's researches salicylic acid is the most powerful chologogue. While the bile salts produce a thick bile, salicylic acid causes an abundant, thin secretion, which is deficient in solid constituents and is well adapted to disintegrate and mobilize biliary calculi. Professor Rosenheim (*Deut. Med. Woch.*, Oct. 2, 1905) reports similarly. Sir James Barr (*British Medical Journal*, Jan. 20, 1906, p. 126) refers to the chologogue action of the salicylates. Professor Ewald (see translation in *Brooklyn Med. Jour.*, Oct., 1905) says that after acute attacks of inflammation or colic, chologogue remedies are indicated, and he prefers bile salts, acid sodium oleate, sodium salicylate, etc.

Problin is "difficult to prepare" because acid sodium oleate is an oily substance, disagreeable to handle, and it would give the pharmacist much trouble to incorporate it properly into a pill with the other ingredients. Certainly the constitution of the pills would vary if the pharmacists were to prepare them, and they would be more expensive. Besides, acid sodium oleate is not kept in stock by druggists, being a special preparation of sodium oleate used by the manufacturers.

We are, of course, in heartiest sympathy with THE JOURNAL's work for ethical and scientific therapeutics, and hence regret all the more the derogatory remarks made on problin, which are doubtless due to an insufficient acquaintance with the remedy.

SCHERING & GLATZ.

[The contention that one of its ingredients is rarely found in stock and that it is disagreeable to handle is in part true, but we repeat that problin can be prepared by any competent American pharmacist. We admit, however, that an article like problin is more likely to be satisfactory if prepared by a reliable and well-equipped manufacturing pharmaceutical house, such as Schering & Glatz represent, than by the average pharmacist.—Ed.]

Correspondence

Interstate Reciprocity.

CHICAGO, Feb. 24, 1906.

To the Editor: In reply to the criticisms of my article on "Interstate Reciprocity," by Dr. E. D. Harrison, secretary of the Michigan State Board of Registration in Medicine, I beg leave to submit the following:

I desire at the outset to state that my article incorporated an educational plan which I proposed as a feasible working scheme and for which neither the Illinois State Board of Health nor the Council on Medical Education of the American Medical Association, with which I have the honor to be connected, are to be held responsible, as the article represents simply my own personal views. I desire to thank Dr. Harrison for calling attention to the words "medical boards" in the sixth paragraph and for the substitution of the word "societies" therefor.

I regret very much that Dr. Harrison seems to have utterly failed to grasp the fundamental ideas which I tried to convey, namely, that the American Medical Association is desirous of assisting the examining boards, and that the plan proposed is not simply a scheme of reciprocity, but a proposed plan of education which, if successfully carried out, will serve as a rational foundation on which reciprocity will naturally rest.

I attempted to anticipate and prevent any criticism of this kind by stating explicitly, at the outset, that "everything relating to the whole subject of medical education belongs to the state." And, again, "The examining and licensing board in each state is the only body authorized to determine the conditions or terms under which physicians are licensed in the state." In order to emphasize still further the fact that the authority of the state is supreme, after outlining the plan of a standard curriculum, in the preparation of which I distinctly state that the leading educators "and members of the examining boards are to unite," I again say, "To establish reciprocity it is only necessary for the states to adopt the standards of the Council on Medical Education." Under the circumstances I see no occasion for the use of such expressions as "usurpation of the authority of the state." Does this look like usurpation of power or authority? Does this imply any intention on the part of the council to assume any of the prerogatives of any of the boards? Does this carry the implication that the medical boards are not "capable of fulfilling the duties and responsibilities with which they are charged by the state"? Does this bear out his accusation that the committee "is entering the field entirely without the range of the committee's power and status"?

Dr. Harrison accuses me of "having omitted in his statement of facts a large percentage of the most material facts connected with and necessary to the success of interstate reciprocity," and yet he adds only two more, namely, the statement that no one school of practice has the authority to settle the question of reciprocity, and that all proper and effective medical laws have been enacted by the co-operation of the several legalized schools of practice. These two statements are true, but wholly irrelevant as far as the present discussion is concerned. We are, therefore, driven to the conclusion either that Dr. Harrison thinks these two points the "most material" in solving the problem, or else that he knows what the most material facts are but fails to state them. Dr. Harrison again says: "It is impossible for Dr. Webster, or, for that matter, any one else, or any association of persons except a state legislature, to confer on the Council of Medical Education of the American Medical Association, of which he is secretary, the authority which he truly states is solely vested in state boards." Once more I must protest that this, although true, is irrelevant. The council does not seek this authority, has no use for it, has not asked for it, has not assumed it and has not hinted that it intends so to do.

Dr. Harrison again says: "These medical boards are capable of fulfilling the duties and responsibilities with which they are charged by the state, and do not require unauthorized persons or associations to measure their authority or to perform their legal duties." This is very gratifying information, notwithstanding its insinuations. What the "capabilities" of the various examining boards are I do not pretend to say. It is my

humble opinion, however, that the boards are not all dominated by men who have given as much serious thought to this subject as has Dr. Harrison, and they have not all done such good work. I am further of the opinion that these boards have not done all they should or could have done and that there are many problems yet unsolved; there is yet much want of harmony of thought and action and purpose; there are too many men going around with chips on their shoulders, fearing some one is going to "un-urp" something and afraid of honest, fearless discussion, jealous of every plan not suggested by themselves. If the profession is wholly satisfied with the "capabilities" of the various boards, why all this discontent in the ranks?

Dr. Harrison "diffidently" begs leave to inform me that some four years ago a confederation of state medical boards was founded, and that "this confederation has succeeded in establishing practical reciprocity with some twenty-one states, including Dr. Webster's own state, Illinois. It has also adopted an itemized standard of preliminary and medical education, which standard has also been adopted and is now being enforced by the Association of American Medical Colleges."

I beg leave to inform Dr. Harrison, without any diffidence whatever, that the National Confederation of State Medical Licensing Boards was founded about ten years earlier than the American Confederation; that the former was the first organization of its kind in the United States to adopt a standard curriculum; that said standard was adopted at New Orleans, May 4, 1903, and modified and again adopted at Atlantic City, June, 1904; that it was proposed by myself, as chairman of the committee on curriculum, that it was modified the next year by me, and that it was substantially this standard curriculum which was adopted without any important modification by the Association of American Medical Colleges, April 10, 1905, and by the American Confederation, April 27, 1905.

In this connection I beg leave to quote a part of a personal letter from Dr. G. M. Kohler, of Washington, D. C., chairman of curriculum committee of Association of American Medical Colleges, dated May 15, 1905, referring to the value of a standard curricula and their adoption by American Confederation and by the Association of American Medical Colleges, in which he says: "In this connection I desire to place myself on record in saying that whatever has been accomplished in this direction during the past year is entirely due to the splendid work which you have performed in this field for over five years, and no one at all familiar with your painstaking tabulations and reports can fail to appreciate the magnitude and immense value of your work, without which my own labors and those of the committee of the Association of American Medical Colleges would have been impossible."

The credit of having first adopted a standard curriculum does not belong to the American Confederation, but to the National Confederation. If these organizations, including Dr. Harrison's confederation, were so ready to adopt a standard uniform curriculum—more or less arbitrary and imperfect though it was, constructed by myself alone, without any legislative authority, without any co-operation of the schools—how much more likely will they and the colleges and examining boards be to adopt a standard if constructed in accordance with the proposed plan?

I beg leave further to inform Dr. Harrison that the Illinois State Board of Health was the first in the Union to offer to reciprocate, and that its first reciprocity resolution was passed Oct. 10, 1899, and it was reciprocating before the American Confederation was born.

His "seventh" in regard to the three schools of practice, and "that no one school, however preponderating (?) its membership, has the authority to settle such a vital question as reciprocity," is true, but irrelevant. If I even remotely suggested such a thing, I am still unaware of the fact. In my plan for a committee on entrance requirements and on standard curriculum it is proposed that the state examining boards be represented, and there is not one word which, even by implication, excludes any school of practice from serving on such committees.

But suppose the committees are made up wholly from the regular school. Let us inquire in what important respects the education of a homeopath or eclectic differs from a regular. All three attend seven years at the grammar school; all three attend the same high school for four years, pursuing the same

studies; all three obtain an arts degree after three or four years of study; all three attend medical colleges in which twenty out of the twenty-three subjects in the curriculum are studied from the same textbooks. In eighteen or nineteen years of study and preparation, a paltry few hundred hours of instruction in materia medica and therapeutics, in which the teaching differs. Would not such eclectics and homeopaths be willing to adopt such a general educational plan if its value, fairness and desirability were demonstrated to them, even though they had no part in its creation? Must one take an active part in the writing of the Bible before he can subscribe to its teaching?

I wish to say, in conclusion, that there is no desire or intention on the part of the Council on Medical Education of the American Medical Association to usurp any of the functions or prerogatives or powers of the examining boards. There is, however, a strong desire to assist these boards and organizations in improving and elevating the standards of entrance requirements and of medical education in every way possible, and to promote harmony and secure intelligent co-operation, and, coupled with this, the confident expectation that interstate reciprocity will follow naturally and legitimately. GEORGE W. WEBSTER.

Organization in Oregon—Further Discussion.

PORTLAND, ORE., Feb. 10, 1906.

To the Editor:—Obedient to the call of its president, the City and County Medical Society of Portland, Ore., convened Jan. 3, 1906, to take action on a letter written by Dr. McCormack to THE JOURNAL of the American Medical Association under the caption, "Oregon Practically an Unorganized State," and also on an editorial which appeared in the same issue of THE JOURNAL based on the letter in question.

The meeting of the society was the largest and most representative in its history, and the discussion which took place was general and of the most animated character. The consensus of thought at the meeting was unanimous and the opinion prevailed that Dr. McCormack by his letter to THE JOURNAL and THE JOURNAL by its editorial did grievous wrong to the profession of Oregon and to its organized societies by publishing the aforesaid letter and editorial and circulating them broadcast, to the detriment of the fair name and credit of the profession of the State of Oregon—a profession, forsooth, which demonstrated beyond all question and cavil its title to being united and well organized, by giving to the American Medical Association one of the most successful sessions that it has ever held.

It is recalled that Dr. McCormack delivered an address to the City and County Medical Society on "Organization," and that at no part of his discourse was there even as much as a hint dropped that his mind harbored such painful impressions concerning the profession of the state and the evils which were corroding and corrupting it. On the contrary, his words carried with them warmth and comfort and made every one feel that he himself felt that his work of organization in the state was satisfactory and sufficient.

Dr. McCormack is reminded that in the discussion which followed his excellent and most interesting address at the meeting referred to there was a very frank avowal of those minor dissensions and differences which exist in all societies, but which found no deeper root in the Portland Society and the profession at large of the State of Oregon than elsewhere, and which were nothing more than surface manifestations of antagonisms which are normal in the modern, strenuous, competitive life.

The City and County Medical Society of Portland, for itself and for the profession of the State of Oregon, resents the charges made in Dr. McCormack's letter and in the editorial columns of THE JOURNAL of the American Medical Association, and characterizes them as unjust and unwarranted.

The society resents and denies the charge that a factional spirit exists obnoxiously in the society that is responsible for the demoralization of the profession throughout the state, and on behalf of its own membership denies the charge that it is divided by factions and that factional spirit is so rife that the society consumes its energies in its internal discords, thereby

nullifying useful effort and hindering all progress, and in answer thereto affirms that the record will show to the unprejudiced investigator that the society has not fallen far short from fulfilling its duties and obligations to the public, to the society and to the profession in all the varied relations that interact between them.

The society resents the charge and denies the truth of the allegation that the most influential members of the profession are outside of the society, and in answer thereto it states that the best elements of the profession are within the society; that the society is actuated by a broad and liberal spirit and has always evinced a readiness and willingness to welcome within its ranks all reputable professional men and women, that it has blackballed none but those who were proved unworthy of being enrolled in its membership on account of flagrant acts of unprofessional conduct.

On behalf of the regular practitioners of the State of Oregon the society resents and characterizes the statement as misleading, mischievous and false that "the average grade of the profession is low and the spirit non-progressive," and in answer thereto respectfully affirms that the great majority (fully 80 per cent.) of the professional men in the State of Oregon now in active practice are graduates of medical schools in excellent standing from the eastern and southern states and from the middle west, and that the charge carries with it a reflection on these schools and the imputation that their graduates and alumni are not worthy or well qualified, and in further answer thereto it is affirmed that it is the progressive spirit which prompts men in all stations in life and all callings to go far and for their chosen spheres of work—that the spirit of the west stands for progress and forever proclaims enterprise.

In behalf of the district and county societies of Oregon, which have not escaped Dr. McCormack's denunciation, the Portland Society avers at this time nothing, inasmuch as Dr. McCormack has so recently visited them, and is, therefore, presumably the better qualified to judge. But in defense of those pioneers of the profession who are striving, under great disadvantages, with limited facilities for communication, to set afoot the intricate and difficult work of organization, it reserves the right to challenge the wisdom of administering a word of rebuke where a timely word of encouragement was most needed.

In defense of the medical schools of the State of Oregon, which are charged with imparting an indifferent standard of medical education, the society has carefully noted Dr. Joseph's letter to THE JOURNAL of the American Medical Association in its issue of Jan. 13, 1906, and, approving its tenor and spirit, commends it to all those who desire to learn the truth regarding the status of medical education in the State of Oregon, and in this connection the society begs leave to say that Dr. Joseph, who has been the dean of the faculty of the Medical Department of the Oregon State University for nearly twenty years, has devoted his best thought and efforts in furtherance of higher standards, and in the prosecution of his work he has enjoyed the undivided support of his colleagues in the faculty, most of whom, being graduates of the best eastern schools, with subsequent European training, are, therefore, pledged to the principle of higher education, and the same may be said regarding the Medical Department of the Willamette University at Salem.

The society has not at its disposal at this time a transcript of the records of the State Board of Medical Examiners, but it believes that the board is striving earnestly to fulfill its functions and to execute the law. The society believes that in its own defense the State Board of Medical Examiners can refute the charges preferred against it by Dr. McCormack that its low standards of requirements have made the State of Oregon the dumping ground for low-grade men who have failed to pass their examinations in neighboring or even distant states. The law is admitted to be defective, but it was the best that could be enacted at the time, and it marked a great forward step, which the society believes will soon be followed by another and greater.

In answer to the charge that the professional fees in the State of Oregon are based on a low standard, the question can be easily solved by reference to the City and County Medical Society fee schedule, which will convince the most skeptical

that, while the schedule may be low in spots, the average is higher—infinity higher—than the average fees in eastern states and the middle west, and will compare very closely with the higher schedules of California and Washington.

The society, acknowledging no disposition on its part to defend the baseness of those who confessed to Dr. McCormack a willingness to debauch their profession and to reduce it with all its glorious traditions to the level of a paltry trade, admits the existence of such evils as Dr. McCormack refers to as "commercialism, division of fees, lodge and other forms of contract practice and kindred evils," but it makes an emphatic denial to the charges that these evils are more pronounced and widespread in the State of Oregon than elsewhere, and Dr. McCormack is respectfully informed that these evils were unheard of and unknown in the State of Oregon until a few short years ago; that the origin of this epidemic or pandemic disorder has been traced to the east and south and middle west; that it has crept slowly to the west, where it has found only limited and partial lodgment, and, furthermore, that the devotees of this nefarious traffic are now known, marked and doomed to the obliquity that awaits them.

Finally, the City and County Medical Society of Portland, for the profession which it represents and for itself, confessing frankly its shortcomings and imperfections and admitting the existence of faults and flaws in its organization, for which at all times it respectfully solicits the aid and co-operation of the parent organization and the wise councils of its accredited representatives, always, however, in respectful form and with due regard to the amenities of polite life, exercises at this time its right to challenge both Dr. McCormack, who is counted an accredited representative of the American Medical Association, and THE JOURNAL of the American Medical Association to establish proofs of the charges and allegation, all of which are herein and hereby categorically denied.

Always mindful of the splendid service that THE JOURNAL of the American Medical Association has rendered and is rendering the medical profession, and its courteous recognition of the efforts of the profession of Oregon at the last session of the American Medical Association, and mindful, also, of the conspicuous service which Dr. McCormack has rendered the profession as missionary in the work of organization and in the interest of higher standards, both in ethics and practice, we remain, for the City and County Medical Society of Portland,

HENRY WALDO COE,

President City and County Medical Society.

GEORGE F. WILSON,

President Oregon State Medical Society.

WALTER E. CAREL,

Ex-President Oregon State Board of Medical Examiners.

KENNETH A. J. MACKENZIE,

Second Vice-President American Medical Association.

P. S.—On account of the unavoidable absence of members of the committee from the state, the transmission of the letter was delayed for a considerable time.

DR. MCCORMACK'S COMMENTS.

To the Editor:—Reading between the lines of the committee's communication, as was the case with Dr. Joseph's letter as to educational matters, there is such constant admission of the discord, commercialism and other evils indicated by me that, but for the repeated declaration that what I had said was "misleading, mischievous and false," and the reiterated challenge that both THE JOURNAL and myself "make good" in the matter, any further comment from me would be unnecessary. As it is, I take up the matter again very reluctantly, embarrassed by the abundance of the corroborative testimony which has come to my hands without seeking, by the seeming harshness of some of the expressions quoted, for which I am not responsible, and still more by the fear of again being misunderstood by leaders so long oversensitive with each other that the most kindly expressed and best intended criticisms were made a new occasion of discord, instead of promoting harmony.

I have before me the published proceedings of the meeting at which this committee was appointed. It was held to consider my report, but the factions went so far afield in protracted and angry crimination and recrimination over matters almost en-

tirely foreign to it as to keep the presiding officer busy preserving order and make what I said of discord seem mild. The profession of Oregon has seen the account of these proceedings, as a number of copies were sent me from out in the state, and it could serve no useful purpose for others to know more of them. The committee says it was an animated meeting, and it certainly was. On the subject of discord between the leaders of the profession, I also quote from a letter of Dr. Walter Brown, Clatskanie, Ore., in the current number of the *Medical Sentinel* (Dr. Coe's journal):

"I will relate an incident in my own experience. About two years ago a fairly intelligent, well-to-do stockman consulted me. His case was so plainly and unmistakably a surgical one that I advised him to go to Portland and have an operation performed. I mentioned three surgeons and told him to consult any or all of them. Instead of remaining in Portland six or eight weeks, as he should have done, he returned in ten or twelve days. He anticipated my surprise and said: 'Doctor, those surgeons in Portland are a pack of snapping, snarling coyotes. I called on Dr. No. 1, who treated me courteously and told me what would have to be done, etc. I next called on Dr. No. 2, and he treated me very politely, but when I told him what Dr. No. 1 had said about my case, I saw he did not like it a bit. Dr. No. 3 was even worse. When I went back to Dr. No. 1 and told him what Drs. Nos. 2 and 3 had said about my case, he grew furious. So I decided about all they cared for was the size of the wad they could get out of me and each was afraid the other would get it, and I said to myself they could go to h—l. I went to see that Chinese doctor. He treated me for a while, and I felt so much better that he told me I could come home, and he would treat me by mail! It is barely possible that you can imagine my chagrin and mortification at this recital. But I will add that this man had to make a business trip to the home of the city of the A. M. A. JOURNAL and while there had an operation performed.'"

In regard to the administration of the medical law, I submit the following letter from one who reports an actual experience:

"—ORE., Jan. 6, 1906.

"Dr. J. N. McCormack, Bowling Green, Ky.

"Dear Doctor:—From the enclosed clipping (*Portland Oregonian*) you will see that your missionary work in our state has already done some good, and I wish to congratulate you for telling the truth so well. Your criticism of the State Board of Medical Examiners was especially timely, for I believe that no poorer board ever existed, and the standard of the profession can never be raised until a new board is formed.

"When I took the examination for my license some four years ago, it was ludicrously easy, and yet every man, with the exception of Dr. Clouche—an Ann Arbor graduate—and myself, cribbed very openly, in plain view of the examiner in charge. The common method was to copy the examination directly from books which they had either on the desks or on their laps, but a few had been industrious enough to prepare 'ponies'. In the anatomy examination, when one old fellow couldn't find what he wanted in the book, Dr. ——— very kindly wrote out the answer and said, 'That's the way I want it answered,' and then winked very broadly at me as he handed it to him. The evening after Dr. ——— examinations, we met him as we were coming out of the Marquam Theater, and Dr. Clouche asked him why he didn't try to stop the cribbing which was so flagrant and disgusting. He replied that the board had decided that any man who was bright enough to crib was bright enough to pass any examination they might give him.

"After some hesitation I joined the local branch of the State Medical Society some two years ago. . . . Were it not compulsory to belong to it in order to remain in good standing in the American Medical Association I would certainly withdraw from the same. . . .

"Trusting that I have served to help convince you that the criticisms you made were justified, and that the state needs a new board of examiners, I am,

"Yours very truly, "—"

To show that was not an isolated example, I quote again from Dr. Brown's letter in Dr. Coe's journal:

"At the time of my examination I saw applicants consulting notes and books pretty freely in making out their papers; however, that has nothing to do with the grade of the examination or the examiner, but it was the faulty method of holding the examination."

Similar support could be given for every other material statement made by me if necessary. In this connection it may be proper for me to say that I did not make the acquaintance or receive a word of information from any physician in Portland who was not a member of the City and County Society, and that I have used no letters or information since not furnished by the members of that organization or the State Society. That my purposes were not so generally misunderstood, even in Portland, except by those who are such important factors in the conditions criticised, I quote the following from one of the most prominent of the younger physicians, a kind of letter which might be multiplied indefinitely from out in the state:

"PORTLAND, ORE., Dec. 16, 1905.

"My Dear Doctor:—I wish to commend you on your article in THE JOURNAL of December 9, and I hope, representing as I do the younger profession, that the influence of your recent visit and your just and timely criticism of our organization will soon bear fruit. The profession has been coming closer and closer together the last few years, and you have given this coalescence a marked impetus.

"I hope you can come to Oregon again; I hope you will make definite plans to do so, because in just such sections your influence on those who are stubborn, and encouragement to those who are striving, is just what is needed."

And at a later date the following from the same gentleman:

"I am sorry that many of the members of the society to which I belong have taken the wrong view of your communication to THE JOURNAL on the Oregon organization, and I hope the committee, which was appointed to reply to you, will 'cool off' a little, and consider the spirit in which you wrote the communication, and the motives which prompted you in doing so.

"The wording of your criticism was taken very literally, and very much to heart, but it is one of those misunderstandings which will be adjusted in the course of time, and soothed down by the cooling balm of sober second thought.

"With the compliments of the season, I am,

"Very truly yours,

"—"

If space permits, Mr. Editor, I will join in the request that my article and the correspondence with Dr. Joseph be reproduced as an introduction to the report of the committee, that the whole subject may be considered together, and especially that the kind and conciliatory spirit which has actuated me from the beginning may be extended to the enforced introduction of matter here which might otherwise seem harsh.

In conclusion, this visit to the Pacific Coast had long been in contemplation and had no connection with the session of the Association in Portland. While a representative of that body, I alone am responsible for my conclusions and for their publication, and if there seems anything ungracious on the part of the Association, or in the editorial comments of THE JOURNAL, which were based on what had been reported by me, I ask that the entire responsibility be laid at my door. It was all said in a spirit of kindness, which no misunderstanding there can either pervert or alter. Such factionalism and rivalry as exists in Portland, estranging, as it does, the families and friends of these excellent, worthy men, is not normal, healthful or universal, as the committee, from long familiarity with such conditions, insists and believes, and is no less hurtful to every interest of both the profession and people because it continues in some other equally unfortunate localities. If these gentlemen would only be as kind and generous with each other in their every-day relations as they are to visitors, these conditions would soon be ancient history, as they should be. No one

[2. It is our opinion that no good will be accomplished by taking the space to reproduce the communications referred to. Those who are anxious to read them will find the communications in THE JOURNAL, Dec. 9, 1905, pp. 1804 and 1818.—Ed.]

[1. The current number of the *Medical Sentinel* states that all three of these physicians have since left the state.—Ed.]

would be more benefited by such hearty, cordial co-operation than these leaders and surgeons, and lesser benefits would soon extend to every other physician, and especially to the younger element in the profession, and I again urge that it be tried, confident, from long experience and observation, that it will do all that is promised.

J. N. McCORMACK.

Medical Forgeries—the Hagen Burger Case.

DENVER, Feb. 19, 1906.

To the Editor:—Dr. J. C. Connell's letter in THE JOURNAL, February 17, contains certain misleading statements relative to the now famous Hagen Burger case that I can not allow to go without correction. By reference to my article on "Medical Forgeries" in THE JOURNAL, February 3, it will be seen that in the second paragraph of his letter he has misquoted the sentence relative to the power of revocation vested in the Colorado licensing board. He has changed the past tense of the verb to have to the present.

In criticising the board's failure to convict Hagen Burger of the criminal charge still pending against him, as compared with the inability, thus far, of the Queen's University senate to revoke the diploma when they know was secured on fraudulent representation, Dr. Connell fails to take into consideration the greater difficulty one encounters in securing a conviction on a criminal charge than in prosecuting a civil suit. Furthermore, under the old Colorado statute extradition was impossible, and he should not criticise us for failure to convict a fugitive from justice.

I am not aware of apologizing for allowing Hagen Burger to escape conviction of the charge still pending in Colorado, nor is there anything in my article threatening to "place certain disabilities on all Queen's College graduates coming to Colorado." The Colorado board and the plan of medical licensure are too broad in their treatment of applicants for license to resort to anything so small. No qualified graduate of Queen's University need fear mistreatment at our hands.

The following from my article with reference to the action of the senate does not sound like criticising Queen's University for not "immediately canceling the degree granted to Hagen Burger":

"Their senate is now conducting an investigation of the case, in which those of their faculty in charge of matriculation and examination of candidates for graduation were most ingloriously duped, and to do other than to revoke the diploma granted Hagen Burger by their college would gain that institution a most unenviable reputation with the medical boards throughout the world."

Why will not Dr. Connell frankly admit that the faculty was duped by the obsequious Tonten, and proceed as vigorously as the Canadian law will permit to revoke his diploma obtained by securing advanced standing through fraud? A trip to Europe is not necessary to prove it.

S. D. VAN MEETER.

Secretary-Treasurer Colorado State Board of Medical Examiners.

Pauper Fees by Wealthy Corporations.

BEDFORD, IND., Feb. 19, 1906.

To the Editor:—I inclose a schedule of fees of the Maryland Casualty Company, Baltimore. The Maryland Casualty Company is sending this schedule to all physicians who act for them, and possibly some physicians will sign the schedule without considering that it means just about one-half of the former fees. I wrote the company that it would be impossible for me to sign it. For such a company, in its present prosperous condition, to ask us to accept such inadequate fees is simply preposterous. The idea of a surgeon accepting \$3 for amputating a finger or \$15 for trephining! If the profession will stand together it will be much better off.

C. H. EMERY.

[The schedule of fees, which has been referred to by several correspondents, asks surgeons to make visits where minor surgical operations are required, such as confused, incised or lacerated wounds, for \$1. This amount is paid also for the removal of foreign bodies from the eye.

Three dollars for the amputation of fingers, for reduction of fractures of the hands or feet, or for dislocation of the bones

of the hands or feet, or for ligating an artery below the knee or elbow.

The generous fee allowed for dislocation of the shoulder, elbow, wrist, ankle or jaw, or for treating fractures of the scapula, fibula, clavicle, ribs, arm, forearm or jaw, is \$5.

For fracture of the femur, tibia or patella, \$10.

The liberal allowance of \$15 is made for trephining the skull, removing the eye, reducing a dislocation of the hip joint or amputating the forearm, or for the excision of the larger joints except the hip joint.

The company becomes extremely generous toward the end and gives \$25 for amputation of the hip or shoulder joint, or excision of the hip joint, or for amputation of the thigh or of the leg.

Then, if more than one patient is treated in the same locality and at the same visit, the above charge is allowed for one, but for all over one only one-half is allowed. Further, if the person injured has received more than one injury the surgeon is paid for treating the most serious injury only, and so on.

We agree with our correspondent that if the profession will stand together they will not be insulted with such contemptible offers as those made by the Maryland Casualty Company of Baltimore.—Ed.]

Quinin in Pneumonia.

ALBUQUERQUE, N. M., Feb. 19, 1906.

To the Editor:—I have read with great interest the article "Pneumonia" appearing in THE JOURNAL, Feb. 10, 1906, by Dr. W. J. Galbraith. Why Dr. Galbraith should claim originality in this course of treatment, however, I fail to see. Dr. A. J. Giesy, attending physician to the Good Samaritan Hospital, Portland, Ore., pursued the course of treatment, to my knowledge, in 1894, and how much earlier I do not know, and as house physician to the Good Samaritan Hospital at that time I have repeatedly administered, by Dr. Giesy's directions, from 30 to 50 grains of quinin at the initial dose and have pursued a like course at different times during the subsequent twelve years. I do not, by any means, think that this measure should be put forth as a matter of routine, but many patients in the first stage of pneumonia are doubtless greatly benefited, and it may about a case—if one's judgment of such an event is to be accepted.

J. B. CUTLER, M.D.,

Surgeon in Charge, Santa Fé Coast-Line Hospital.

Marriages

HENRY W. HERYFORD, M.D., Anderson, Cal., to Mrs. C. E. Corbin of Springfield, Mo.

HARRY J. BRUCE, M.D., to Miss Mary Elizabeth Morrison, both of Chicago, February 7.

P. H. WILLIAMS, M.D., to Miss Sibyl Stafford, both of Paintsville, Ky., February 7.

E. D. JACKSON, M.D., Newcastle, Pa., to Miss Sue Anderson of La Rue, Ohio, February 16.

ROBERT N. CUMMINGS, M.D., Emmett, Idaho, to Miss Harriet Reynolds of Boston, February 19.

DANIEL A. STINE, M.D., to Miss Florence Rebecca Harris, both of Philadelphia, February 14.

WILLIAM WHITALL REQUAET, M.D., to Miss Chesley Chen-ton, both of Baltimore, February 10.

MARTIN M. GROVE, M.D., Dell Rapids, S.D., to Miss Grace Fiske, at Plainview, Minn., January 1.

CHARLES R. DANCER, M.D., Fort Wayne, Ind., to Miss Catherine Rusk of Wayland, Ind., February 19.

EDWARD W. WINTER, M.D., White Plains, N. Y., to Miss Eleanor Jackson of Ottawa, Ont., February 7.

CLEMENT ELLIS CONGER, M.D., Cross Keys, Va., to Miss Hallie Ramsey, at Alexandria, Va., February 21.

J. GEMMILL CHICHESTER, M.D., Bedford, S. D., to Miss Frances Reeves Mettler of Chicago, February 24.

FRANCIS A. STORLUS, M.D., Denver, Colo., to Miss Adelaide N. Shell of New York City, at Burlington, Iowa, February 14.

HARRY C. MARXMEILLER, M.D., Newport, Ky., to Miss Ednah Tinker Gruwell of Los Angeles, Cal., at Bluffton, Ind., February 22.

Deaths

Thomas Ross, M.D. McGill University Medical Department, Montreal, 1863; a member of the American Medical Association; ex-president, secretary and assistant secretary of the Medical Society of the State of California; president of the Sacramento Society for Medical Improvement; a member and for eight years president of the Sacramento board of health; physician to the Southern Pacific Railroad Hospital; in 1878 county physician of Yolo County, and for a long time secretary of the Woodland board of health, died at his home in Sacramento, February 11, from cerebral hemorrhage, after an illness of three weeks, aged 65.

Thomas J. Bergen, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1859; surgeon of the First Pennsylvania Infantry during the Civil War; for more than twenty years a member of the staff of St. Elizabeth's Hospital, Utica, and a member of the active or consulting staff of the Utica General Hospital since its foundation; a member of the board of charities and later of the board of town auditors of Utica; a member of the Oneida County Medical Society, died at his home in Utica from heart disease, February 15, after an illness of three months, aged 72.

William Wilson Torrence, M.D. Rush Medical College, Chicago, 1880; a member of the American Medical Association, Illinois State Medical Society and Black Hills Medical Society; honorary member of the North Central Illinois Medical Association; member of the American Association for the Advancement of Science; formerly a well-known physician of Deadwood, S. D., and prior to that time a missionary of the Presbyterian board in Teheran, Persia, and physician to the Shah, died at St. Joseph's Hospital, Denver, February 13, after a long illness, aged 50.

Wesley Davis, M.D. Harvard University Medical School, Boston, 1866; a member of the American Medical Association for many years; a veteran of the Civil War; counselor of the Massachusetts Medical Society; a member of the visiting staff and for a long time a trustee and president of the board of trustees of the Worcester City Hospital; one of the oldest practitioners of Worcester, died at his home in that city from cerebral hemorrhage, after an illness of two weeks, aged 65.

Thomas Kelley, M.D. Rush Medical College, Chicago, 1871; a veteran of the Civil War; for thirty-five years a physician of the Santa Clara Valley, Cal.; for one term county physician, and once president of the Santa Clara County Medical Society; from 1899 to 1904 postmaster of San José, Cal., died at his home in that city, February 14, from fatty degeneration of the heart, after a long illness, aged 69.

Thomas Chappell Cook, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1859; health physician of Colorado County, Texas, for several years; assistant surgeon of the First Texas Heavy Artillery, C. S. A., during the Civil War; a member of the state legislature in 1885 and 1886, died at his home in Weimar, Texas, February 19, from nephritis, after a long illness, aged 69.

James B. Sherry, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1868; a veteran of the Civil War; for several terms medical director of the Department of Massachusetts, G. A. R.; a member of the Fusilier Veteran Association and of the Ancient and Honorable Artillery Company, died at his home in Boston, February 21, from heart disease, aged 62.

George W. Stone, M.D. Bellevue Hospital Medical College, New York City, 1876; a member of the American Medical Association, and one of the most highly esteemed practitioners of Lapeer County, Mich.; for more than twenty years a member of the school board, died at his home in Metamora, Mich., February 13, from heart disease, after an illness of a year, aged 60.

William Valentine McKenzie, M.D. College of Physicians and Surgeons in the City of New York, 1884; a member and president of the Middlesex County (N. J.) Medical Society, and president of the board of education and a member of the board of health of Metuchen, died at his home in that city, February 13, after an illness of four months, aged 44.

Alfred Martin Vollmer, M.D. American Medical Missionary College, Chicago, 1902; a member of the American Medical Association; for two years a practitioner in Apia, Samoa, and vice consular general of the United States at that point, died at his home in Milton, Wis., February 15, from pulmonary tuberculosis, after an illness of several months, aged 30.

David Fawcley, M.D. College of Physicians and Surgeons in the City of New York, 1864; the oldest practitioner of Watertown, N. Y.; a medical cadet in the Army, and later a surgeon in the United States Navy during the Civil War, died in Watertown while making a professional call, February 13, from cerebral hemorrhage, aged 68.

Francis E. North, M.D. College of Physicians and Surgeons, Chicago, of Taylorville, Ill., a member of the Illinois State Medical Society and Christian County Medical Society, died at the Missouri Baptist Sanitarium, St. Louis, February 20, from intestinal obstruction, eight days after an operation for appendicitis, aged 27.

William E. Mattison, M.D. College of Physicians and Surgeons in the City of New York, 1852; surgeon of the Third New Jersey Volunteer Infantry during the Civil War; for many years justice of the peace of North Plainfield, N. J., died at his home in that city, February 11, from heart disease, aged 82.

Warren P. Blake, M.D. Dartmouth Medical School, Hanover, N. H., 1884, a member of the Springfield Medical Club, Hampden District Medical Society and Massachusetts Medical Society, died at his home in Springfield, Mass., February 15, from disease of the liver, after an illness of two months, aged 47.

William Barber, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1865; one of the oldest practitioners of Waverly, Iowa; once coroner of Bremer County; a surgeon during the Civil War, died in Waverly, from heart disease, February 10, after a short illness, aged 75.

A. Henry Butts, M.D. Medical College of Virginia, Richmond, 1858, a surgeon in the Confederate service during the Civil War and until a few months ago a practitioner of Greenville, Monroe County, W. Va., died at his home in Charleston, W. Va., February 7, from pneumonia, aged 72.

William H. Murphy, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1899; a famous Yale athlete and coach; athletic instructor in the United States Naval Academy, Annapolis, Md., died in Westboro, Mass., February 14, aged 35.

John H. Cochran, M.D. New York University, New York City, 1867, of The Plains, Va.; a veteran of the Civil War; representative of Fauquier and Loudoun counties in the Virginia legislature, died in Richmond, February 24, from cerebral hemorrhage, aged 63.

James M. Rix, M.D. Bellevue Hospital Medical College, New York City, 1868, a Civil War veteran, some-time member of the school board of Warner, N. H., died at his home in that place, February 16, from cholelithiasis, after an illness of a year, aged 72.

Andrew Milton Miller, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889, for several years health officer of Alpena, Mich., died from malignant disease of the stomach at his home in Detroit, February 16, aged 42.

Pennick Browning Rogers, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, a member of the staff of the Maiman Eye and Ear Hospital, New York City, died in New York, February 11, from pneumonia, aged 25.

Eley H. Harrison, M.D. University of Nashville (Tenn.) Medical Department, 1896, city physician of Texarkana, Texas, for two years, died at a sanitarium in Memphis, Tenn., February 15, after an operation for appendicitis, aged 35.

Charles H. Chubb, M.D. Jefferson Medical College, Philadelphia, 1856, of Palenville, N. Y., for a number of years president of the Greene County (N. Y.) Medical Society, died in Mount Vernon, N. Y., February 16, aged 72.

Howard Carey, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885, of Tenstrike, Minn., died at the Beltrami County Hospital, Bemidji, Minn., from nephritis, February 13, after a long illness.

David Onslow Smith, M.D. Harvard University Medical School, Boston, 1850, well known as a physician and musical composer, died at his home in Hudson Center, N. H., February 15, after a long and painful illness, aged 82.

Harry Martyn Brace, M.D. College of Physicians and Surgeons in the City of New York, 1881, mayor of Perth Amboy, N. J., died at his home in that city, February 19, from nephritis, after an illness of six months, aged 46.

Benjamin B. Ferguson, M.D. Jefferson Medical College, Philadelphia, 1893, a member of the Camden County Medical Society, died suddenly at his home in Camden, N. J., February 12, from cerebral hemorrhage, aged 53.

Benjamin Franklin Grant, M.D. Homeopathic Hospital College, Cleveland, Ohio, 1867, of Bath, N. Y., died at the Coburn Sanitarium in that city, February 17, from general nervous breakdown, after a long illness, aged 78.

L. A. Wilson, M.D. St. Louis Medical College, 1864, assistant surgeon of the Forty-fourth Missouri Volunteer Infantry during the Civil War, died at his home in Cuba, Mo., February 17, after a short illness, aged 78.

A. Perry Bowman, M.D. Chicago Homeopathic Medical College, 1878, president of the Iowa Homeopathic Medical Society, died suddenly at his home in Sioux City, from heart disease, February 19, aged 49.

William Gaines Kibbe, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1878, a Confederate veteran, of Abbeville, La., died suddenly from apoplexy in that city, February 12, aged 64.

Eleanor Rolshausen, M.D. Woman's Medical College of Chicago; formerly of Logansport; county physician of Cass County, Ind., for two terms, died at her home in Royal Center, Ind., February 9, aged 72.

James Murphy, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1866, died at his home in Bangor, Mich., February 13, from cerebral hemorrhage, after a short illness, aged 63.

Hugh J. Sullivan, M.D. University of Wooster Medical Department, Cleveland, Ohio, 1889, coroner of Wayne County, Ohio, died at his home in Congress, from poison taken accidentally, February 24.

Oliver D. Coppedge, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1857, of Concrete, Texas, died in Cuero, Texas, February 9, from pneumonia, after a short illness.

W. Dixon Norwood, M.D. National Medical University of Chicago, 1895, was thrown from his buggy in a runaway accident at Shreveport, La., February 14, and almost instantly killed, aged 36.

Warren Elliott Harrigan, M.D. New York University, New York City, 1885, of Williamsburg, N. Y., died suddenly from heart disease while making a professional call, February 14, aged 43.

William Wallace Munn, M.D. New York University, New York City, 1868, died at his home in Lansing, Mich., February 10, after an illness of ten months from malignant disease, aged 66.

E. Jansen Westfall, M.D. College of Physicians and Surgeons in the City of New York, 1871, died at his home in Rahway, N. J., February 18, from pneumonia, after a brief illness, aged 59.

Walter K. Wadleigh, M.D. Dartmouth Medical School, Hanover, N. H., 1887, died at his home in Hopkinton, N. H., February 7, from nephritis, after a long illness, aged 41.

John Page Burwell, M.D. Jefferson Medical College, Philadelphia, 1880, formerly of Millwood, Va., died recently in Washington, D. C., from heart disease, aged 53.

William H. Cleckler, M.D. Missouri Medical College, St. Louis, 1897, of Gowen, I. T., was drowned while being ferried across Gaines Creek, near Gowen, February 12.

Everett F. Hamilton, M.D. University of Louisville (Ky.) Medical Department, 1889, died at his home in Austin, Texas, February 11, from heart disease, aged 41.

Jacob W. Du Bois, M.D. Bellevue Hospital Medical College, New York City, 1865, died at his home in Millersville, Md., from heart disease, February 19, aged 70.

Thomas B. Lyon, M.D. Kentucky School of Medicine, Louisville, 1880, died at his home in Upland, Ind., February 8, from asthma, after a long illness, aged 53.

Herman Levi Cook, M.D. McGill University Medical Department, Montreal, 1854, died at his home in Toronto, Nov. 16, 1905, from pneumonia, aged 74.

Oscar K. Johnson, M.D. Kentucky School of Medicine, Louisville, 1891, died suddenly at his home in Queens, W. Va., February 18, aged 35.

Morris T. Judah, M.D. (County License, Indiana, 1897), of Gent, Ind., died in Bloomington, Ind., February 14, from heart disease, aged 65.

Henry W. Robertson, M.D. Harvard University Medical School, Boston, 1872, died recently at his home in Crapaud, P. E. I., aged 61.

Charles H. Barnhardt, M.D. Jefferson Medical College, Philadelphia, 1895, died at his home in Concord, N. C., February 7, from pneumonia.

Edwin V. Tegart, M.D. University of the Victoria College, Coburg, Ont., 1859, died at his home in Brantford, Ont., Sept. 9, 1905, aged 70.

George I. McKenzie, M.D. Jefferson Medical College, Philadelphia, 1864, died at his home in Pieton, N. S., in August, 1905, aged 67.

John Gillies, M.D. McGill University Medical Department, Montreal, 1867, died at his home in Teswater, Ont., Aug. 15, 1905, aged 68.

Herman J. Van der Linden, M.D. University of Utrecht, Holland, 1884, of Delmont, S. D., died suddenly in that place, February 10.

William Hunter Carson, M.D., passed assistant surgeon, U. S. P. H. and M.-H. Service, died at Belize, British Honduras, July 25, 1895.

D. H. Harrison, M.D. McGill University Medical Department, Montreal, 1864, died at his home in Vancouver, B. C., recently, aged 63.

Benjamin A. Penn, M.D. Eclectic Medical Institute, Cincinnati, 1865, died at his home in Bryantsburg, Ind., February 10, aged 82.

Mark A. Perkins, M.D. Kentucky School of Medicine, Louisville, 1867, died at his home in Hastings, Neb., February 13, aged 65.

C. E. Bailey, M.D. Michigan College of Medicine, Detroit, 1881, of Orange, Mich., died recently in Ionia, Mich., aged 54.

Deaths Abroad.

L. de Wecker M.D., the famous ophthalmologist, died at Paris, February 13, aged 74. He was born in Germany and studied at Berlin, Vienna and Paris, practicing as a physician in France and Russia until 1862, when he settled in Paris and devoted himself to practicing and teaching ophthalmology. It was not then taught in the medical colleges as a special science. The list of his works and of the instruments and operations which he devised is a long one.

W. H. Gilbert, M.D., died at Baden, February 11, aged 48. He was known as a popular physician, a balneologist and proprietor of a sanatorium, but his fame rests principally on his suggestion of the medical study trips, which he inaugurated six years ago with great success from the start.

A. Gusserow, M.D., professor of obstetrics and a well-known writer on obstetric and gynecologic topics, died at Berlin, February 6, aged 69. He has been co-editor of the *Archiv f. Gynakologie* since 1884.

Miscellany

TYPHOID FEVER PROPHYLAXIS.

Report on the Methods Employed in the Campaign Against Typhoid in Germany.

E. D. W. GREIG, B.Sc., M.B., C.M.

Captain Indian Medical Service, Deputed by the Secretary of State for India to investigate the methods.

1. INTRODUCTION.

In order to study the various methods employed in the campaign against typhoid fever in Germany, permission was obtained, through the Foreign Office, for me to go to Germany and investigate the subject there. I reached Berlin Sept. 25, 1905, and was advised to study the methods, in the first instance, at the Kgl. Institut für Infektionskrankheiten. This I did until Oct. 22, 1905, on which date I proceeded to certain of the institutes for antityphoid work to study the practical application of the methods. I visited the institutes at the following places: Saarbrücken, Neunkirchen, Metz, Diedenhofen and Trier. At these places I studied the routine method of examination of the material sent in, and accompanied the superintendent on several occasions into the district to see the methods adopted in investigating outbreaks of typhoid fever in the villages. I was thus enabled to gain an insight into the practical working of antityphoid measures in Germany.

I desire to express my heartiest thanks to Professor Dr. Kirchner (*grch. ober. medicinischer und vortragender rat. in ministerium d. geist. und medicinalen anlegenheiten*) for his advice and help, to Geh. Med. Rat. Professor Dr. Gadfly, director of the Kgl. Institut für Infektionskrankheiten, and

to Prof. Dr. P. Frosch, with whom I worked at the institute, for his constant courtesy, and to the superintendents of the institutes at Saarbrücken, Neunkirchen, Metz, Diedenhofen and Trier for affording me every facility for investigation.

2. FACTS OF IMPORTANCE IN CONNECTION WITH ANTITYPHOID MEASURES.

(a) Typhoid fever is spread to a large extent by the bacilli being directly carried from the sick to the healthy, e. g., infection of food, the use of contaminated eating and drinking utensils, etc. In this form of so-called "contact" infection the epidemic has a gradual onset and prolonged course. Should the bacilli gain access to a water supply used by a number of persons, then a large number of cases occur simultaneously—the so-called "explosion epidemic." The workers in Germany have found this latter mode of infection of comparatively rare occurrence as compared with the former.

(b) Living bacilli may continue in the feces and urine for long periods after the fever has ceased, and persons who give no history of previous attacks of typhoid fever, but who have been in contact with typhoid cases, may also harbor the bacilli in their stools. This group of cases is a very important one from the prophylactic point of view; they are the "bacilli carriers" of the Germans. These individuals are, in fact, "reservoirs" of the parasite and play an analogous part to the wild game in Nagana, which harbor the trypanosomes without any apparent signs of disease.

(c) The disease may run a very mild course, particularly in young children, and thus a number of cases may escape observation. The detection of these cases forms a very important part of the antityphoid work.

(d) A disease closely resembling typhoid fever, clinically, but caused by a totally distinct organism—*B. paratyphosus*—may occur at the same time as typhoid fever.

3. IT IS NECESSARY TO ORGANIZE SCIENTIFIC INSTITUTES NEAR THE TYPHOID EPIDEMIC TO PUT INTO PRACTICE THE ABOVE PRINCIPLES.

The German Government has founded eleven institutes, each with a superintendent and two or three trained scientific men, as well as one or two attendants, for the antityphoid campaign in Alsace-Lorraine. These institutes are fully equipped for the scientific work required. They are chiefly engaged in the prevention of the spread of typhoid among the civil population. The military population, which is a large one, has a similar organization, and, the conditions being much more favorable for carrying out the antityphoid measures, the results show a satisfactory reduction of typhoid fever among the troops.

Each institute has its defined area of work, but they also keep in touch with one another. The extent of the area of work is determined by the density of population, e. g., Trier, which is situated in a sparsely populated district, has a very extensive area, while those of Saarbrücken, Saarbrücken and Neunkirchen are small, the population being very dense near these places. The institute receives its material from the various medical men in charge of the cases, and the members go out into the villages and towns with the district medical officer of health and investigate the details of the origin of the epidemic. As far as possible, each epidemic is traced back to its source. It is necessary to determine: (i) whether cases are imported ones; (ii) whether the infection is carried by water; (iii) whether carried by food; (iv) whether carried by men affected by typhoid fever, e. g., family epidemic; (v) whether a local focus of endemic typhoid, so-called "typhoid house," exists. In carrying into practice these lines of investigation certain lists kept in every village are examined in the first instance; these are: (a) list kept by police of reported arrivals in the village; (b) the list of attendance at the schools; (c) the sick list (*Krankenkassenlisten*); (d) the list of deaths reported. From these lists valuable information is obtained, which forms a starting point for further investiga-

tion. It is generally found that the actual number of cases of typhoid fever far exceeds that which has been reported. The water supply, milk supply and general sanitary condition of the village are carefully inquired into, and the result of these, along with the result of the bacteriologic investigations, is entered in a special form, which is called *Fragebogen*, which contains thirty-nine headings, which are classified under (1) general, i. e., position and character of place, water and milk supply, etc.; (2) special, which contains details regarding patient, the disinfection carried out and the result of the bacteriologic investigations; (3) result of the case, whether it ended in death or recovery; the results of final bacteriologic investigation, and what sanitary improvements have been carried out.

The suspected cases having been picked out by the help of the information obtained from the above-mentioned sources, it is next necessary to examine the blood, feces and urine of each at the laboratory. The blood is taken in capillary tubes. For the urine and feces, special glass tubes, fitted with a metal spoon in the cork and carefully inclosed in a tin and wooden box, are left at the house. Directions are given to the nurse or friends to place three or four spoonfuls of the feces in one tube, which is packed and the box carefully labeled; some urine is also placed in another tube. These are forthwith dispatched to the institute. It is important for the investigation that they should be as fresh as possible. When these are received at the laboratory they are examined at once. The result of the examination is communicated to the medical man in charge of the case and the medical officer of health, who have the necessary disinfection and isolation carried out. When possible the isolation is carried out in special hospitals; otherwise the medical officer of health gives the necessary instructions to the friends for the isolation of the patient in the house. For the purposes of disinfection the liquor cresosoli saponatus or the German Pharmacopoeia is used. The eating and drinking utensils are immersed in it. The stools and urine, which are received in special vessels, are mixed with it. After the patient is entirely free from fever, the stool and urine are examined three times at intervals of ten days, and the patients are not allowed to leave the hospital until the result of the bacteriologic investigation shows them to be free from bacilli. It is found necessary to do so three times, as relapses are not infrequent, especially in the fourth week of convalescence, in which case the examinations have to begin afresh.

Having thus considered the general plan of work, it is necessary to consider:

4. TECHNIC FOR EXAMINATION OF MATERIAL FROM SUSPECTED CASES.

As a matter of practical routine, the following examinations are made:

(1) *Blood*.—The usual Widal reaction, carried out both microscopically and macroscopically. The test is made both with typhoid and paratyphoid bacilli. It may be observed that a positive Widal reaction is no proof that the present illness of the patient is typhoid fever, but a reaction, which is at first negative and then becomes positive, is absolute proof.

(2) *Feces and Urine*.—The examination of these for the presence of *B. typhosus* and *paratyphosus* is all important. Unfortunately we have not yet discovered an ideal method for the detection of *B. typhosus* in feces; its recovery from the urine is a simpler matter. We have not got an "enriching" process similar to the peptone water for the detection of the vibrio of cholera. The newer methods, however, are a distinct advance on our older methods, and no doubt further advances will be made.

The following are the methods used: V. Drigalski and Conrad¹ Malachite green method of Lentz.² Fuchsin agar method of Endo.³ Caffeine-fuchsin agar method of Gaeltgens.⁴

1. Drigalski and Conrad: Zeitschrift für Hygiene und Infektionskrankheiten, vol. 39, 1202.

2. Lentz and Tiez: "Weitere Mittheilungen über die Anreicherungs-methode für Typhus und Paratyphus bacillen mittelst einer Vaccin- und malachite grün agar." From Klinischen Jahrbuch: Gustav Fischer, Jena, 1905.

3. Endo: Centralblatt für Bakter., vol. xxv, p. 109.

4. Gaeltgens: Centralblatt für Bakteriologie, 1 abt. orig., vol. xxxix, No. 5, p. 634.

In the institutes visited, either the Drigalski-Conradi method alone was employed or in combination with the malachite green method. The Endo method was employed in Diedenhoften, as well as the others. Each method has its advantages and disadvantages, but it is certain that rapidly in detecting the typhoid colonies is largely a matter of experience and practice, and an observer who is accustomed to recognize it on one medium may fail to do so on another. The details of the mode of preparation of each of these are given:

A.—PREPARATION OF DRIGALSKI-CONRAI MEDIUM.

(I) *Agar Preparation*.—To three pounds of finely cut horseflesh add two liters of water. Allow it to stand till next day. The excess juice is boiled for one hour and filtered. Add 20.0 gr. peptone, Witte, 20.0 gr. nitroase, 10.0 gr. NaCl; boil one hour, now add 70 gr. bic agar, then boil three hours (or one hour in autoclave), render slightly alkaline (indicator litmus paper). Filter, boil half an hour.

(II) *Litmus Solution*.—Litmus solution (Kohel and Tieman) 260.0 c.c., boil for ten minutes, add milk sugar (chemically pure) 30.0 gm., boil fifteen minutes.

(III) *Agar*.—Add the hot litmus-milk-sugar solution to the liquid agar solution cooled to 40° C. Shake well. Render it again faintly alkaline. The color of the froth is a good indicator. Add then 2.0 c.c. of a hot sterile solution of 10 per cent. water-free soda, further add 10.0 c.c. of a freshly prepared solution of 10 gr. crystal violet B. in 100 c.c. of warm water (distilled).

One has now a meat-water peptone-nitroase agar with 13 per cent. litmus and 0.01 per mille crystal violet. This can be poured directly into plates and the remainder kept in 200 c.c. flasks.

B.—THE MALACHITE GREEN ENRICHING METHOD OF LENTZ.

The proper preparation to use is malachitgrün (crystal) (Höchst) diluted in distilled water. The solution is made by dissolving finely divided, macerated with two liters of water for sixteen hours. The extract is expressed, boiled for half an hour, filtered, then 3 per cent. agar added and boiled for three hours; add to the agar 1 per cent. peptone, 0.5 NaCl, and 1 per cent. nitroase (this may be omitted). This is brought to the litmus neutral point by soda solution with Duplittest paper. Boiled one hour, filtered through linen. The reaction of the finished agar is sometimes distinctly acid.

Before the addition of the malachite green, the hot agar is tested by Duplittest paper and so far alkalinized with sterile soda solution until the red strip is distinctly red-violet. This reaction point corresponds to normal nitroase, to an alkaline degree of 18 per cent. normal soda below the phenolphthalein-neutral point; if the agar contains nitroase, which remains neutral toward litmus and bacteria, then the alkaline reaction corresponds to 3.5 per cent. normal soda solution below the phenolphthalein point. Add 0.25 c.c. of the hot agar 1 c.c. of a 1-22 solution malachite green (the solution keeps good for ten days) is added, i. e., agar contains 1-22-0000. By this concentration of malachite green (crystal) the growth of the usual typhoid bacilli, as well as many other fermenting organisms, is greatly diminished and practically prevented. The *B. typhosus* growth is also diminished, but only so far that after twenty-four hours the colony can be recognized with the naked eye, the size of a particle of sand, while after a longer period in the incubator, in two to four days, larger, stronger colonies appear which color the agar yellow.

The finished agar is poured at once into Petri dishes in 2 mm. thick layers. The dishes are well dried.

C.—THE FUCHSIN-AGAR METHOD OF ENDO.

In an enamel pot put two liters of water (stap), 20.0 gr. Liebig's meat extract, 15.0 gr. peptone, Witte, 10.0 NaCl, and 80 gr. bic agar. Boil, filter, neutralize. Add 10 gr. chemically pure milk sugar and 10 c.c. of 10 per cent. crystallized fuchsin in 96 per cent. alcohol. Then the medium becomes dark red in color. Now add 25 c.c. of a 10 per cent. sodium sulphite solution. The medium becomes gradually decolorized, but only completely so when the agar is stiff. Sterilize in small tubes for thirty minutes. Pour into plates.

D.—THE CAFFEIN-FUCHSIN AGAR METHOD OF GAETZENS.

Preparation of the Medium.—As a result of his experiments, Gaetz has found that 0.35 per cent. chemically pure caffeine in Endo's medium (described above), which had an alkalinity equal to 1.5 per cent. normal KOH below the neutral point of phenolphthalein, markedly increased the value of the medium as a means of detecting the typhoid bacilli.

Endo medium, prepared in exactly the same way as described by himself, is liquified, made alkaline to the required degree, and the required amount of caffeine added.

In all these methods attempts are made, with more or less success, to check the growth of members of the coli group and to encourage the development of the *B. typhosus* and *paratyphosus*. In the Drigalski and Conradi method, crystal violet is used; in the Lentz method, malachite green; in the Endo, fuchsin; and Gaetzens, caffeine. At the same time the typhoid colonies are differentiated from the coli group by a color reaction. In Drigalski the typhoid colonies are blue and the coli red. In the Endo the coli colonies turn bright red, while the typhoid colonies are colorless. In both cases the fact that *B. coli* produces acid in presence of milk sugar is made use of. In the one case, litmus, and the other, decolorized fuchsin. A color reaction is thus obtained in both cases.

Malachite green checks the growth of both coli and typhoid very markedly, but more especially coli. Accordingly, when a stool is planted out on such an agar plate, if may not be possible at the end of twenty-four hours to detect any colonies of typhoid. Lentz has found, however, that if such a plate is

flooded with normal salt solution and gently rocked and then allowed to stand for a few minutes the delicate typhoid colonies diffuse themselves in the solution, while the solid coli colonies sink to the bottom, so that if a little of this fluid is plated out on Drigalski plates practically a pure growth of *B. typhosus* or *paratyphosus* may be obtained. In practice it is found that *B. paratyphosus* is readily "enriched" in this way, but the *B. typhosus* not to the same extent.

Having thus seen the method of preparation of the different culture media and principles of their use, it is next necessary to consider the method of preparation and inoculation of the plates with the feces and urine. The following are the steps:

1. *Preparation of the plates*.—In this investigation it is more convenient to use a larger size of Petri dish than that generally used. It should be from 15 to 20 centimeters in diameter. About 20 to 25 c.c. of the medium is poured into each plate. The plates are allowed to remain open until all the steam has evaporated and the agar is stiff. It is essential that the surface of the plates should be quite dry and firm. Contamination by air-organisms does not occur on account of the aniline dye present in the culture media.

2. *Preparation of the Feces*.—The feces are thoroughly mixed with a small quantity of sterile normal salt solution. Then, when one malachite green plate is used in combination with two Drigalski plates, about 0.5 c.c. of the mixture is placed on a green plate. This amount may also be used with the caffeine-Endo, but with the Drigalski plates about a much smaller amount, about one or two loopfuls, is sufficient.

In the case of urine, several drops are placed on the green plates, on the Drigalski plate one drop is sufficient.

Having thus got the prepared material on the first plate, the next step is the smearing. This is done in the same way, whether green and blue, or all blue, plates are used.

3. *Smearing of the Plates*.—A sterile glass rod, which has had its terminal end bent at right angles, is used.

The material on the first plate is thoroughly smeared by rubbing the glass spatula, as it is called, in all directions over the surface of the agar. Then, without sterilizing it, the same spatula is rubbed over the surface of a second plate, and then over a third and fourth, and so on, smearing the plates as they are allowed to stand upon till quite dry. The plates are then placed in the incubator at 37° C., and left there for twenty to twenty-four hours. At the end of this period the next step is examination of the colonies.

THE EXAMINATION OF THE COLONIES.

It will be convenient to state briefly the characters of the colonies on the different media already mentioned.

1. *Drigalski-Conradi*.—By this method the first plate is so overgrown that it is useless for further examination. The second, third and fourth, however, are carefully inspected. It is very desirable to use a hand lens for this purpose, as the direct light so that the light falls from a wall, not directly from the window, as a better contrast between the colonies is obtained. After a good deal of practice, it is possible to recognize immediately a colony of *B. typhosus* on the plate even if only a single one exists, but at first it takes a considerable amount of time, because a large number of colonies are found which closely resemble those of *B. typhosus*, and it is, therefore, necessary to test each of them according to the methods described later. Broadly stated, the *B. coli* colonies are more or less red in color, not transparent, and from 2 to 3 millimeters in diameter, while the *B. typhosus* colonies have a diameter of from 1 to 3 millimeters. The color is blue with a dash of violet; they resemble dew drops.

2. *Colorless Endo, Malachite Green and Drigalski Method*.—As will be remembered, the first plate in this method was malachite green agar, and the second and third Drigalski-Conradi. At the end of twenty hours the second and third plates are examined and present the same characters as noted above. If typhoid colonies are found on these plates then the investigation is finished, but, if they are not, it is possible by a further procedure to detect them, and this is the special merit claimed for this method. The procedure is this: The green plate is flooded with sterile normal saline and gently rocked, and then allowed to stand for a few minutes. By this means it is found that the more delicate typhoid and paratyphoid colonies readily diffuse themselves in the liquid, while the heavier coli, as a hard rule, sink to the bottom. The glass spatula is then dipped in the salt solution and rubbed on one or two Drigalski-Conradi plates, which are placed in the incubator at 37° C. for twenty hours. When examined they exhibit the same characters as this method of "enriching" gives very good results with *B. paratyphosus*; the *B. typhosus* is not "enriched" to the same extent, but still it is an additional means of detecting this organism, and in the hands of Lentz has yielded good results.

3. *Endo Method*.—Here all the coli colonies are bright red at the end of twenty hours, and therefore, very easily separated. The typhoid colonies are colorless and very transparent. A stool plated on this medium gives a very striking contrast with the normal saline method, but not to the same extent as the blue plates. If a very large number of coli organisms are present the plate is liable to become entirely red, and this interferes with the examination of the typhoid colonies. On the whole, this medium answers a very useful one for the separation of *B. coli* and *B. typhosus*.

4. *Gaetzens Caffein-Fuchsin Agar*. The appearance is essentially the same as that on the Endo plates, but the growth of *B. coli* is markedly inhibited.

Having thus seen the general appearance of the colonies, the next step is:

THE IDENTIFICATION OF SUSPECTED TYPHOID COLONIES.

In practice this is done as follows: A portion of the colony is touched with a very fine platinum needle and placed in a

INFORMATION WANTED ABOUT DR. COLIN M'KINZIE.

Dr. J. B. Carroll, Hatboro, Pa., and Mr. Webster A. Melcher, 1124 Girard Bldg., Philadelphia, have been endeavoring in vain to learn something about Dr. Colin McKinzie, who wrote or delivered some lectures on gynecology some 125 or more years ago. Copies of these lectures were owned by one J. S. Thompson in 1784. Any facts or suggestions as to avenues for inquiry will be welcomed.

"DISTRIBUTION OF COEFFICIENT."

—, Colo., Feb. 18, 1906.

To the Editor:—Can you explain to me "distribution of coefficient" used in the article "Theory of Narcosis" by Meyer, in THE JOURNAL, Jan. 29, 1906? He bases his premises on that table. What was his mixture of fat and water? How does he obtain his distribution coefficient? He has aroused my interest, but did not exactly satisfy me. A. J.

ANSWER.—By "distribution coefficient" is meant the proportion of a given substance that is distributed between two or more different solvents. This may be illustrated as follows: Suppose we have a substance which is twice as soluble in benzine as it is in water, and we shake it up in a flask containing a mixture of equal parts of benzine and water. Part of the substance will be dissolved in the water, and just twice as much will be dissolved in the benzine. This proportion of 2 to 1 will be the "distribution coefficient," or, as it is usually called, "partition coefficient" of the substance in a mixture of water and benzine. The common laboratory practice of extracting many organic substances that are highly soluble in ether, from watery solutions, by shaking up a mixture of the watery solution and ether in a suitable container depends on this principle.

In Professor Meyer's experiments, the narcotic to be studied was shaken up in a mixture of equal parts of fat and water, and the proportion of the narcotic that was taken up by the fat and the proportion taken up by the water were ascertained. The relation of the amount of narcotic dissolved by the fat to the amount dissolved by the water constitutes the coefficient. For example, if in a given experiment 4 grams of tetralin were dissolved in the fat and 1 gram in the water, the coefficient for tetralin in this mixture would be 4 to 1 or 4.

State Boards of Registration

COMING EXAMINATIONS.

MAINE State Board of Registration of Medicine, City Building, Portland, March 13. Secretary, Wm. J. Maybury, Saco.
CONNECTICUT Medical Examining Board, City Hall, New Haven, March 13-14. Secretary, Charles A. Tuttle, New Haven.
MASSACHUSETTS Board of Registration in Medicine, State House, Boston, March 13-14. Secretary, Edwin B. Harvey, Boston.

Arizona October Report.—Dr. Ancil Martin, secretary of the Board of Medical Examiners of Arizona, reports the written examinations held at Phoenix, Oct. 2-3, 1905, and Jan. 1-2, 1906. At both examinations the number of subjects examined was 9; total number of questions asked, 90; percentage required to pass, 75.

At the October examinations the total number of candidates examined was 9, of whom 8 passed and 1 failed. The following colleges were represented:

College.	PASSED.		Per Cent.
	Year Grad.		
Kentucky School of Medicine	(1905)	79.2	
College of P. and S., Baltimore	(1904)	80.7	
Casper Med. Coll., San Francisco	(1896)	75	
University of Iowa	(1897)	76.9	
Rush Med. Coll.	(1903)	76.3	
University of Pennsylvania	(1903)	80.2	
Jefferson Med. Coll.	(1900)	81.6	
Denver College of Medicine	(1901)	83.4	
FAILED.			
University of Louisville	(1904)	49.3	

At the January examination the number of candidates examined was 10, of whom 9 passed and 1 failed. The following colleges were represented:

College.	PASSED.		Per Cent.
	Year Grad.		
American Med. Coll., St. Louis	(1892)	75	
College of P. and S., San Francisco	(1904)	75	

drop of highly active serum, in dilution 1-100, on a slide and carefully mixed; at the same time a control should be made with a drop of normal saline solution placed alongside. The agglutination, if it occurs, may be observed with a hand lens or low power of the microscope. Both typhoid and paratyphoid sera are used. In this way a large number of colonies can be rapidly examined. Should complete agglutination occur, then the remainder of the colony is inoculated into tubes containing various nutrient media. From the academic point of view, a considerable number of these are required, but in practice it is found that about three amply meet all the necessities, of which ordinary agar slope, litmus whey and neutral red agar or grape-sugar are most commonly used.

The following is a complete list of the different media, with the methods of preparation:

(a) *Barakow milk sugar*.—Made thus: (1) 5 gr. nutrose, 0.5 gr. NaCl, aqua distill. 100 c.c. Sterilize, filter several times to clarify (2) 5 c.c. litmus solution (Kubel and Tieman) 1 gr. milk sugar or grape sugar or mannite, maltose, etc. Sterilize six to eight minutes. Cool to 60 per cent. Mix (1) and (2). Sterilize for ten minutes on three successive days.

(b) *Mannite*, as above.

(c) *Barakow's grape sugar*, as above.

(d) *Litmus whey*: 500 c.c. milk; add 10 to 12 c.c. N/1 solution HCl to precipitate casein. Neutralize with soda solution. Boil one to two hours. Let the precipitate fall to the bottom. Take 100 c.c. of fluid and add 5 c.c. litmus solution. Plate in tubes, sterilize two to three hours at 100 C.

(e) *Neutral roth agar*: Agar 2 per cent., grape sugar 0.5 per cent., neutral roth solution 1 c.c. (saturated watery solution of Ehrlich's neutral roth). Mix; sterilize.

Should the agglutination be positive in 1-100 dilution of serum, and the organism gives characteristic reactions in the various media, the diagnosis of typhoid or paratyphoid, as the case may be, can then be made. Only in exceptional cases is it necessary to perform the Pfeiffer experiment.

The above is a description of the routine examinations made at the institutes. In addition to the urine and feces it may occasionally be necessary to examine the expectoration from the lungs, pus and postmortem material. The procedure is exactly similar to that adopted in the examination of feces.

To determine the presence of typhoid bacilli in the blood it is necessary to take about 5 c.c. from a vein and add to it a large quantity of sterile bouillon to neutralize the bactericidal substances present in the blood.

The determination of *B. typhosus* in water is not very satisfactory.

The above is an outline of the methods adopted in the campaign against typhoid in Germany.

It will be readily seen that in a civil population the practical difficulties are enormous. Isolation can not be carried out in many cases, and the disinfection of the urine and feces must be left in the hands of the individual himself, and whether the instructions are implicitly followed is at times questionable. So under these circumstances the progress must be slow. On the other hand, in the army it ought to be a simpler matter, because there the individuals are constantly under observation and discipline. It is a matter of common knowledge that to send a person harboring the parasites of disease back among a number of uninfected individuals is a sure method of lighting up fresh infection. The danger of typhoid infection is that the individual, although appearing perfectly well, may harbor the bacilli and so infect others. The point of importance to remember is that only by repeated bacteriologic examination of the feces and urine are we in a position to say when a man can safely return to duty without being a source of danger to his neighbors; and, further, only by this examination can the latent foci of the disease be discovered; these unrecognized harborers of the disease, the "bacilli carriers," are the chief means by which the disease continues to spread, in spite of all improvements in sanitation.

After these investigations have been continued for some time we get a valuable accumulation of scientific facts, which enables us to intelligently correct real hygienic faults.

It is an interesting fact that methods based on the same principles are employed in Germany to combat the spread of cholera, and our methods for the detection of the cholera vibrio are much more perfect than those for the *B. typhosus* in feces, because we have in peptone water an excellent "enriching" medium for the vibrio of cholera.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending Feb. 24, 1906:

Steer, Samuel L., asst.-surgeon, ordered to accompany Troops B and M, 3d Cavalry, from Fort Assiniboine, Montana, to Presidio of San Francisco. On completion of this duty Captain Steer will return to his station.

Reilly, John J., asst.-surgeon, retired from active service with the rank of captain, on account of disability incident to the service, to date from Feb. 4, 1906.

Wright, W. D., surgeon, leave of absence extended until such time as will enable him to rejoin station after return of the transport *Sumner* to New York City.

Kirkpatrick, Thos. J., asst.-surgeon, left Fort Moultrie, S. C., on ten days' leave.

Kleber, Chas. F., surgeon, left Fort D. A. Russell, Wyo., on ten days' sick leave of absence.

Ruifier, E. L., asst.-surgeon, left Columbus Barracks, Ohio, with recruits on route to Fort Worden, Wash.

Pears, Caspar K., contract surgeon, returned to Fort Sam Houston, Texas, from leave of absence.

Parkman, Wallace E., contract surgeon, returned to Fort Assiniboine, Mont., from leave of absence.

Wadell, Ralph W., dental surgeon, left San Francisco for duty in the Philippines Division.

Wing, J. B., dental surgeon, relieved from duty at Fort Riley, Neb., and ordered to duty at Fort Omaha, Neb.

Landerdale, Clarence E., dental surgeon, left Fort Logan H. Routs, Ark., and arrived at Fort Reno, Okla., for duty.

Robert, Michael A., contract surgeon, returned from temporary duty at Fort Schuyler, N. Y., to Fort Totten, N. Y.

Boyer, Arthur J., contract surgeon, left Fort Apache, Ariz., and arrived at Fort Huachuca, Ariz., for duty.

Reazles, James, contract surgeon, left Fort Yellowstone, Wyo., and arrived at Fort Kough, Mont., for duty.

Boyer, Arthur J., contract surgeon, ordered from Kinsbridge, N. Y., to Fort Jay, N. Y., to accompany the 8th Infantry thence to Philippine service.

Cook, William H., contract surgeon, ordered from Gravesend, N. Y., to Fort Niagara, N. Y., to accompany the 8th Infantry thence to Philippine service.

Navy Changes.

Changes in the Medical Corps U. S. Navy, for the week ending Feb. 24, 1906:

Tyree, E. W., acting asst.-surgeon, detached from the Naval Training Station, San Francisco, and ordered to the Naval Recruit Station, Kansas City, Mo.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Feb. 21, 1906:

Rosenau, M. J., P. A. surgeon, detailed to attend meetings of committee of American Bacteriologists in New York, N. Y., Feb. 24, relative to the standardization of tetanus antitoxin sera.

Moore, Dunlop, P. A. surgeon, relieved from duty at Yokohama, Japan, and directed to proceed to Honolulu, Hawaii, reporting to Chief Quarantine Officer for duty.

Currie, D. H., P. A. surgeon, department letter of July 27, 1905, amended so as to grant P. A. Surgeon Currie twenty-one days' leave of absence from July 18, 1905, instead of two months.

Birkhalter, J. T., P. A. Surgeon, granted seven days' extra leave of absence from February 24.

Frissell, C. M., acting asst.-surgeon, granted twenty days' leave of absence from February 14.

Hallett, E. B., acting asst.-surgeon, granted five days' leave of absence from February 19.

Townsend, E., acting asst.-surgeon, granted seven days' leave of absence from February 14.

Waters, M., pharmacist, department letter of January 30 amended so as to grant Pharmacist Waters thirty days' leave of absence from February 8, instead of February 15.

BOARD CONVENED.

Board of officers convened to meet at the bureau, February 27, for the purpose of making physical examination of an officer of the Revenue Cutter Service in detail for the board. Assistant Surgeon General W. J. Pettus, chairman; Assistant Surgeon J. W. Trask, recorder.

APPOINTMENT.

Albert J. Nite appointed acting assistant surgeon for duty at Port Huron, Michigan.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ending February 23, 1906:

SANALAPPO—UNITED STATES.

California: Los Angeles, Feb. 3-10, 2 cases; San Francisco, 13 cases.

Florida: Jacksonville, Feb. 10-17, 9 cases.

Georgia: Augusta, Feb. 12-19, 10 cases.

Louisiana: New Orleans, Feb. 10-17, 17 cases.

Maine: Bideford, Feb. 10-17, 1 case.

Maryland: Baltimore, Feb. 10-17, 4 cases.

Michigan: Ann Arbor, Feb. 10-17, 1 case.

Missouri: St. Louis, Feb. 10-17, 3 cases.

Montana: Missoula County, Jan. 1-31, 1 case; Silverbow County, 1 case.
Nebraska: South Omaha, Feb. 10-17, 2 cases.
New York: Buffalo, Jan. 10-31, 1 case; New York, Feb. 10-17, 1 case.
Ohio: Cincinnati, Feb. 9-16, 9 cases.
Tennessee: Knoxville, Feb. 10-17, 1 case.
Wisconsin: Appleton, Feb. 10-17, 2 cases; Milwaukee, Jan. 27-Feb. 3, 1 case.

SMALLPOX—FOREIGN.

Brazil: Bahia, Dec. 8-30, 25 cases, 2 deaths; Pernambuco, Jan. 1-15, 43 deaths; Rio de Janeiro, Jan. 7-28, 15 cases, 1 death.
Chile: Antofagasta, Jan. 18-Feb. 1, 34 cases, 17 deaths; Coquimbo, Jan. 18-Feb. 1, 3 cases.
China: Canton, Dec. 25-31, 40 cases; Hong Kong, Jan. 6-13, 1 case; Shanghai, Dec. 30-Jan. 6, 1 case, 2 deaths.
France: Paris, Jan. 27-Feb. 3, 12 cases.
Great Britain: Bristol, Jan. 27-Feb. 3, 5 cases.
Greece: Athens, Jan. 13-22, 1 death.
India: Bombay, Jan. 16-23, 5 deaths; Calcutta, Jan. 6-13, 55 deaths; Karachi Dec. 26-Jan. 2, 3 cases; Madras, Jan. 13-19, 12 deaths; Rangoon, Jan. 6-13, 14 deaths.
Italy: General, Jan. 27-Feb. 1, 39 cases.
Mexico: Tuxpan, Jan. 31-Feb. 13, 5 deaths.
Russia: St. Petersburg, Jan. 20-27, 5 cases.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Jan. 7-28, 8 cases, 6 deaths.
Ecuador: Guayaquil, Jan. 8-28, 20 cases, 12 deaths.

CHOLERA—INSULAR.

Philippine Islands: Manila, Dec. 23-Jan. 6, 5 cases, 5 deaths; Provinces, Jan. 11, present.

CHOLERA—FOREIGN.

India: Calcutta, Jan. 6-13, 61 deaths; Madras, Jan. 13-19, 1 death; Rangoon, Jan. 6-13, 1 death.

PLAGUE—INSULAR.

Philippine Islands: Manila, Dec. 23-30, 1 case, 1 death.

PLAGUE—FOREIGN.

Brazil: Pernambuco, Jan. 8-15, 2 deaths; Rio de Janeiro, Jan. 7-28, 9 cases, 1 death.
Chile: Antofagasta, Jan. 18-Feb. 1, 2 cases, 1 death.
China: Hong Kong, Jan. 6-13, 2 cases, 2 deaths.
India: General, Jan. 6-13, 1,351 cases, 1,140 deaths; Bombay, Jan. 16-23, 31 deaths; Calcutta, Jan. 6-13, 16 deaths; Karachi, Dec. 26-Jan. 2, 9 cases, 7 deaths; Madras, Jan. 13-19, 4 deaths; Mouline, Jan. 20, 1 death; Rangoon, Jan. 6-13, 18 deaths.
Japan: Kobe, Dec. 9-Jan. 11, 36 cases, 30 deaths; Jan. 13-20, 2 cases, 2 deaths; Osaka, Dec. 9-Jan. 11, 73 cases, 62 deaths.
Peru: Callao, Jan. 12-25, 1 case; Lima, 7 cases, 5 deaths; Mollemdo, 6 cases, 2 deaths; Paíta, 1 case; Trujillo, 25 cases, 10 deaths.

Book Notices

THE RIVAL TRIUMPH OF JAPAN: The Conquest of the Silent Ego. By Louis Livingston Scamman, M.D., LL.D., late surgeon-major U. S. V. E. Cloth. 291 pages. Illustrated. Price, \$1.50. New York: D. Appleton & Company, 1906.

In the dedication of this book is given the text on which the entire argument is based and which is directly in line with Major Scamman's efforts toward the abolition of the officialism which, he claims, renders ineffective in great measure the work of the undoubtedly able men in the medical department of the United States Army. The dedication reads as follows:

"To the medical and sanitary officers of the Japanese Army, who have proved that the normal condition of the soldier is health, and that those who die in war should fall on the firing line and not by the wayside from disease; to the heroic dead of that army, who have gladly given their lives for the honor and integrity of their beloved country; to that vast army of American dead, whose lives in war have been needlessly sacrificed through preventable diseases, ignorance and incompetency, and to our lawmakers, through whom the necessary reforms can come that will prevent the repetition of such sacrifice, these lines are dedicated."

Dr. Scamman quotes from the statistics of deaths from wounds and from disease in modern wars, demonstrating that in the Russo-Japanese war the ratio was more than reversed on account of the excellence of the hygienic regulations of the Japanese medical department. Sandwiched in between arguments for the reorganization of the Medical Department of the United States Army are interesting narratives of the author's experiences in Manchuria and Japan toward and after the close of the war. He pays especial attention to the system and practice of hygiene in the Japanese Army and gives a most interesting sketch of the history of medical science in Japan. He devotes a chapter to the discussion of beri-beri and its practical extinction in the navy through the researches and exertion of Baron Takaki, and closes with an appeal to the American nation that it should not forget the lessons of the War of the Rebellion and afterward of the Spanish-American War, but should

follow the example of Japan and be prepared to meet emergencies that may arise, with the greatest possible exercise of all that modern medical, surgical, and especially hygienic, science teaches.

A MEMOIR OF DR. JAMES JACKSON, with Sketches of his Father, Hon. Jonathan Jackson, and his brothers Robert, Henry, Charles and Patrick Tracy Jackson; and Some Account of Their Ancestry. By J. J. Putnam, M.D. Cloth. 17p. 456. Price, \$2.50 net. New York: Houghton Mifflin & Co., 1905.

This will be considered a rather belated memoir when it is realized that forty years have elapsed since Dr. Jackson's death, and especially since he had attained to an advanced old age when he died. But, while belated, it is none the less welcome, if for no other reason than that it is another addition to the literature that enlightens us regarding medical affairs at the time when American medicine was in the forming.

Dr. Jackson was one of the most influential of the physicians in and around Boston during the first quarter of the nineteenth century. While he wrote but little that has come down to us, or that left an impression on medical literature, he was one of those who influenced the affairs of his time and who molded professional and public opinion, not only for the then present, but for the future. He returned from his European studies in 1800, just at the time that vaccination was being introduced, and to him belongs the credit of being the first physician in this country to have absolute confidence in the Jenner theory. He had obtained this confidence from his experiences in the small-pox hospitals of London under Dr. Woodville, the enthusiastic follower of Jenner. Dr. Jackson was a contemporary with Dr. John Collins Warren, and the two were co-workers in many schemes for the betterment of the profession and for improved hygienic conditions of the public. These two were the leaders in the reorganization of the Massachusetts State Medical Society, Dr. Warren being the first president of the new society; and the Massachusetts General Hospital owes its inception to Drs. Warren and Jackson, the former having the credit for conceiving the idea. Thus in the memoirs before us we are carried back to those good old times that we all like to read about, to the time when character and integrity and hard work were the ideals. Nearly half of the volume is devoted to a history of Jackson's ancestors, and these and their times are described in an interesting, if not a charming, manner.

To those who love to read of men who have done things, and of the early history of our country, especially as it relates to medicine, these memoirs will be found both satisfactory and pleasing.

THE ART OF COMPOUNDING. A Text-book for Students and a Reference Book for Pharmacists at the Prescription Counter. By Wilbur L. Scoville, Ph.D., formerly Professor of Theory and Practice of Pharmacy in the Massachusetts College of Pharmacy. Third edition. Revised and enlarged. Cloth. Pp. 357. Price, \$2.50 net. Philadelphia: P. Blakiston's Son & Co., 1904.

Now that the physician is beginning especially to concern himself as to the character and composition of medicines, a book should be welcome which affords information as to how best to prepare many of the pharmaceutical mixtures extemporaneously. While the work is based on the eighth revision of the U. S. Pharmacopoeia and the official preparations are used as examples, most unofficial related classes are included with similar illustrations; thus, for instance, under "Miscellaneous External Preparations" are described cataplasms, fomentations, plaster-mull, plasma, escharotics, pastes, paints, collodion, drying liniments, glycerogelatin, pencils or crayons, salve pencils, spongipiline and moxa. Specimen combinations are here given and they afford the physician an endless variety of prescription. There is, besides, much valuable information on writing prescriptions, incompatibilities, etc. In plasters, however, the author describes the commercial manufacturer of rubber plasters without referring to the far more valuable therapeutically official plasters made of the adhesive plaster of the new Pharmacopoeia, which any physician may use to advantage.

NERVOUS AND MENTAL DISEASES. By Archibald Church, M.D., Professor of Nervous and Mental Diseases and Medical Jurisprudence in Northwestern University Medical School, Chicago; and Frederick Peterson, M.D., President of the State Commission in Lunacy, New York. Fifth edition, revised and enlarged. Octavo. 937 pages, 341 illustrations. Cloth, \$5.00 net. Philadelphia: W. B. Saunders Co., 1905.

The preface states that practically no very material changes have been made in the arrangement or descriptive text, though the work as a whole has been carefully revised and many brief

interpolations made to improve the subject-matter. This is more strictly true of the section on nervous diseases. The changes are more notable in Dr. Peterson's section on mental disorders. In the former editions the old-style classification of the classic types of mania, melancholia, dementia, etc., was retained almost intact, notwithstanding the fact that the ideas of the Heidelberg school had already begun to tinge the ideas of many American psychiatrists. In this edition Dr. Peterson has included Kraepelin's species of "manic-depressive" insanity and "dementia præcox," though not according them exactly the same limits and extension as is done by Kraepelin and his followers. He also retains the old forms of mania and melancholia, in which, especially as regards the latter, he will probably find many practical alienists in accordance with him. Dr. Adolf Meyer's elaborate essay on the recent problems of psychiatry is retained in this edition and furnishes a valuable exposé of the modern European views. The book as a whole will deservedly retain the public favor with which the former editions were received.

RADIO-THERAPY IN SKIN DISEASE. By J. Belot, with a Preface by L. Brocq. Translated by W. D. Buicher, M.R.C.S. Authorized translation from the Second French Edition, with thirteen plates and twenty-eight illustrations. Cloth. Pp. 463. New York: Robman Company, 1905.

The first part of this book is a historical review of radio-therapy: production of x-rays, including sources of electricity, the various currents, tubes, etc.; methods of exact measurement, and the theory of the Roentgen rays. Part II deals chiefly with the biologic effects of rays and the method of application. Part III takes up the treatment of various diseases. From the descriptions given, the apparatus and technic seem rather complicated. The quantities of rays used are expressed according to the units of the Holzknecht chromoradiometer. The work will be of more value to specialists in electrotherapeutics and dermatology than to the general practitioner.

AROUND THE WORLD VIA INDIA. A Medical Tour. By N. Senn, Ph.D., LL.D. Cloth. Pp. 347. Chicago: American Medical Association Press, 1905.

This book consists of a series of most interesting letters, written by Dr. Senn while traveling, which first appeared serially in *THE JOURNAL*. Beginning with Hawaii, Dr. Senn describes the manner and customs of the peoples, with diseases peculiar to the various countries visited. He writes instructively of the leper colony in Hawaii, giving an eloquent tribute to the work of Father Damien, and describes the condition of medical education in Australia and in India. He speaks highly of the work done by the men of the Indian Medical Service, especially in regard to research work in cholera and plague serums and antivenin. This book is well illustrated, showing characteristic people, buildings and scenery.

DEVELOPMENTAL PATHOLOGY. By E. S. Talbot, M.S., D.D.S., LL.D. First Edition. Cloth. 265 illustrations. Chicago. Published by the Author, 1905.

Dr. Talbot has gathered in this volume articles which he has written on various phases of the subject treated and which he has published from time to time in various medical and dental journals. The contents of the work indicate the extent of the author's research, not only in stomatology, but over a wide field of medical subjects, and embody the results of thirty years' labor. The subject of evolution was little understood thirty years ago, and these various articles prove the accord with that theory shown in most of the deformities of the human body.

LECTURES ON AUTOINTOXICATION IN DISEASE, OF Self-Poisoning of the Individual. By Ch. Bonchard. Translated with a Preface and New Chapters Added by T. Oliver, M.A., M.D., F.R.C.P., Professor of Physiology, University of Durham. Second Edition. Cloth. Pp. 342. Price, \$2.00 net. Philadelphia: F. A. Davis Co., 1905.

This book is about twice as large as the original volume by Bonchard which bore the same title. It has been rewritten by Thomas Oliver, who made the original translations. The new matter has been interpolated and added to the old. In its present form it contains the numerous additions which have been made to medicine in the field which it covers.

ATONIA GASTRICA (Abdominal Relaxation). By A. Rose, M.D., and R. C. Kemp, M.D. Cloth. Pp. 293. Price, \$1.00 net. New York: Funk & Wagnalls Co., 1905.

This work treats an important subject in a superficial way.

It would be of greater use to the general practitioner were there fewer digressions into the field of etymology. A large part of the book is devoted to reports of cases in which the patients were treated by a plaster bandage devised by one of the authors. Methods, new and old, of diagnosing this condition are briefly related.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Veronal.

Veronal as a hypnotic has come into use more and more within the past year or two, especially in the treatment of insomnia due to functional nervous disturbances, such as neurasthenia, hysteria, etc. It is best given in doses of from 5 to 7½ grains (.30-.50) each, and prescribed in the powder form. The sleep that it induces undoubtedly more nearly approaches the normal sleep than that produced by other hypnotics of the same class. Its advantages, therefore, lie in the fact that the usual drowsy feeling which the patient complains of during the day following the taking of bromids or sulphonal, are usually absent. In the experience of reliable authorities, patients state that the sleep thus produced is almost a natural sleep, and a refreshed feeling is observed after the patient awakens. With this preparation, as with all other hypnotics, however, there are a number of cases on record of poisonous effects produced by taking this preparation in too large doses. In *THE JOURNAL*, February 17, page 550, it is noted that poisoning from veronal took place after the ingestion of 4.5 grams (68 grains). The same symptoms of nausea, vomiting, headache and somnolence have been observed after the self-administration of 75 grains (5.00) of chloralal-mid by a patient who was endeavoring to secure sleep after a prolonged debauch. The preparation was the elixir of chloralal-mid, taken in teaspoonful doses every few minutes, which was probably because of the presence of the alcohol in the mixture.

The "Practical Medicine Series" recommends veronal in the treatment of insomnia due to epilepsy, general paralysis, neurasthenia and hysteria. It is recommended that it be given in warm water on retiring. Its action is rapid, and within half an hour a quiet, natural sleep, without disagreeable prodromal sensations, is experienced. The duration of sleep from administration of from 5 to 7½ grains (.30-.50) of this preparation was six hours. The patients, according to this authority, do not establish a toleration for the drug or become accustomed to it. The circulation and the digestive systems are not disturbed, and the secretions of the body show no modification. The precaution, however, is given of observing the state of the liver and kidneys before its administration. Späthmeyer, in the same periodical, regards veronal as a hypnotic of value, given in gram doses (grains 15) at bedtime. Other authorities finds its taste less disagreeable than that of chloral, paraldehyde or dormiol, and its action superior; at the same time, it does not show the cumulative action of sulphonal and trional. Patrik endorses this preparation as a very commendable one, and has used it a great number of cases, and has not observed an instance of decidedly unpleasant effects. He regards the dose of ½ gram (grains 7½) as sufficient in mild cases, and even 5 grains will be effective in such cases. He regards 15 grains as a dose which may be given without hesitation when it is deemed necessary, although he states that some somnolence and slight dizziness may be noted the following day. He quotes one case in which 30 grains were given by mistake, and the only ill effect was very prolonged slumber, followed by some dizziness and uncertainty on the feet.

D. R. Brower usually prescribes it in doses of 5 grains (.30) each, and in preference to increasing the dose of veronal he

combines with it codain in doses of from 1/4 to 1/3 grain (.015-.02), and he prefers this preparation in the ordinary cases of insomnia to the bromids or even to chloralamid, which he formerly used in preference to the other hypnotics, on account of the fact that it had no depressing effects on the heart or circulation.

Gastric Ulcer.

In the treatment of gastric ulcer William Van V. Hayes, in the *New York State Journal of Medicine*, states that when there are repeated severe hemorrhages with cicatricial obstruction, or when there is a carcinoma engrafted on the ulcer, that a competent surgeon should be consulted. If the case is a medical one he recommends rest in bed, usually for four or five weeks, allowing a week or two, if possible, after the abnormal signs and symptoms are controlled. During the first few weeks of rest in bed the patient should not be allowed to sit up in bed for any purpose. The alimentation should be by the bowel, especially in the more severe cases. It is necessary to vary the food according to the needs of each particular case. In other cases milk may be given in quantities of from one-half to one glass every two hours. It should not be very hot nor ice-cold, and should be combined with two ounces of Vichy or lime water. If milk is not well tolerated, the whites of two eggs, beaten up with water, and two ounces of beef juice may be given alternately every two hours. This should be continued for a period of about ten days, until the symptoms are under control, when he recommends strained gruels, the fine wheat cereals or chicken broths, soft boiled or lightly poached eggs, and bread a day or two old. After a few weeks the patient may be allowed a general diet. Rectal feeding should be employed for one or two weeks in the hemorrhagic and severe cases. Cleansing enemata should be given one hour before the nutrient enemata are administered. The latter should be given through a long tube with side openings, and during its administration the patient's hips should be raised on a pillow. Pressure should be made against the rectum so as to retain the enema for twenty minutes, and the patient should be instructed to maintain the same position for from half to one hour. He recommends the following combination for nutrient enemata:

Milk peptonized	5 ounces.
Yolk of egg	1
Claret	1 tablespoonful.
Prepared cereal food	1 tablespoonful.
Salt	15 grains.
Or Milk	4 ounces.
Water	1 ounce.
Eggs	2
Salt	15 grains.

The milk and egg in this preparation may be predigested with pancreatin, 5 grains, and sodium bicarbonate, 15 grains.

Place the receptacle containing this mixture in a wooden bucket containing water as hot as can be borne by the hand, and allow it to remain for one hour. One tablespoonful of arrowroot made into a paste may be added before predigestion.

Another combination similar to the following is recommended as an enema:

Liq. peptones	1 ounce.
Water or peptonized milk	5 ounces.
Salt	15 grains.

If the bowel is irritable, from 3 to 5 minims of the tincture of opium may be added to each enema. In order to control bleeding from the stomach, if present, the nitrate of silver may be given in one-fourth grain doses in half an ounce of water, every morning when the patient awakes, for a period of about ten days, after which bismuth subnitrate may be given in 60-grain doses at bedtime, and continued, if necessary. To counteract the hyperacidity, which is irritating to the ulcer, the following combination is recommended by the author:

R. Bismuthi subcarbonatis	grs. iii	20
Sodii bicarbonatis		
Magnesium bicarbonatis, 55.	gr. v	30

Fiat polysiv No. 1. Sig.: To be given fifteen minutes after food.

In cases of severe hemorrhage, the essential treatment is absolute quiet, hypodermic injection of morphin sulphate, gr. 1/4, combined with atropin sulphate, gr. 1/150, and adrenalin chlorid (1:1,000), 30 drops, diluted in water and given by the mouth. An ice-bag or cold compress should be applied to the epigastrium. If necessary, one pint of warm normal saline solution may be given by the rectum or hypodermically. Nutrient enemata may be resorted to after twenty-four hours.

For the resulting anemia in these cases he prefers the liquid preparation of iron, that is, the tincture, in from 10 to 15 drop doses (.65-1.00), in albumin water, and taken through a tube three times a day.

Formaldehyd in Internal Diseases.

J. Zwilling, in an abstract in the *British Medical Journal*, recommends the administration of formaldehyd internally in cases of sore throat, catarrh of the bladder, erysipelas, scarlet fever and diphtheria. In almost every case favorable results were obtained. He recommends that it be given in the form of mint tablets, each of which contains 1 centigram of formaldehyd. In such a way the formaldehyd is set free in the mouth as the tablet dissolves, and exerts a direct disinfectant and bactericidal action, consequently it is well to instruct the patient to keep the tablets in the mouth as long as possible. He administered these tablets once every hour until five tablets were taken, when the interval between the doses was increased to two hours until the temperature became normal, and then one was given every three hours. This was the dose given to children of ages varying from 5 to 10 years. He speaks of administering it in ten cases of diphtheria as a substitute for the local treatment by disinfectant gargles, and in some of the milder cases antitoxin was not administered. In all these cases improvement was rapid and diphtheritic paralysis did not occur in any. He regards it as of value in the treatment of cystitis, which may be due to gonorrheal origin or spinal conditions.

Medicolegal

Osteopaths Are Practicers of Medicine.

The Supreme Court of Alabama says that the case of Ligon vs. State was tried on an agreed state of facts similar in all essential respects to the case of Bragg vs. State, 134 Ala., 165, in which it was held, June 28, 1902, that the practice of osteopathy was the practice of medicine within the meaning of the code provisions of that state. It says that the object of the appeal in this (Ligon) case was to have the Bragg case overruled. Counsel said, in brief: "It is respectfully submitted that on review of the point involved this court should not affirm the correctness of that decision, but should depart from it." The court's answer is that the decision in that (Bragg) case was unanimous. It covered all of the questions here involved, after careful and mature consideration. The court has re-examined it, and on reason and the authorities cited it has been unable to conclude that it is wrong. It should not, therefore, be overruled. The court can add nothing new in this decision to what was there said. To attempt it would be to go over the same grounds with inability to shed new light on them.

Liability of Wife for Medical Care of Husband.

The Supreme Court of Washington says, in the case of Russell vs. Grammann, an action brought by a physician, that a statute of that state provides: "The expenses of the family and the education of the children are chargeable on the property of both husband and wife, or either of them, and in relation thereto they may be sued jointly or separately." That ordinary medical aid and advice for the wife create family expenses has been repeatedly held. The husband is a part of the ordinary family, and under a statute providing in general terms for liability for "expenses of the family," as does the statute above quoted, the court sees no reason why medical and hospital services rendered to a husband are not as fully comprehended in the statute as are those rendered to a wife. Assuming that in this case the wife may not at any time have been with her husband in

the city of Spokane, where he had resided for about three years pursuing his occupation as a painter, it did not follow from that fact alone that the family relationship had in a legal sense been severed. It is not necessary that the husband and wife shall at all times reside together under the same roof in order that the legal status of the family may be preserved. It is a matter of common knowledge that many husbands in their struggles for a livelihood are often required to be far from home and for long periods of time, and that such enforced absences are in behalf of the family, in order that the comforts of life may be provided for them. Such absence may be a strong evidence of affection and regard for the family, rather than otherwise. It will not do to say that in such cases the family status is destroyed by somewhat continued absence of the husband.

Presumption of Death from Circumstantial Evidence.

The Supreme Court of Kansas says, in *Modern Woodmen of America vs. Gerdum*, that it is true that death may be proved by circumstantial evidence, and that absence for a considerable period of time is not indispensable in order to generate a satisfying conviction of the fact. But in all such instances the death of the absent party must fairly be demonstrated by the circumstances of the disappearance. If, for example, in connection with other facts showing a want of motive for absence, it should appear that the missing person was on a vessel which foundered or a train which was wrecked, or engaged in some hazardous enterprise, or met with an accident which might be expected to result fatally, or was exposed to perils incompatible with his age or the state of his health, or was afflicted with a fatal disease, or was mentally infirm, or was suicidally inclined, belief in the fact of death might be forced on the mind very soon after the disappearance. And in some cases the age, health, disposition, moral character, domestic relations, social rank and financial condition of one who suddenly disappears may themselves, without the aid of other circumstances, stifle all doubt that the person is dead. Such, at least, is the view of most of the courts of last resort. But in all the cases enumerated, lapse of time is in a measure a subsidiary matter. There must be a sufficient opportunity for investigation and search, and after the expiration of a period ample for those purposes further stretches of duration without tidings may confirm the inference of death. But the strength of the induction lies in the cogency of the circumstances of the disappearance and not in the fact of absence long protracted. The social aspects of our civilization have been almost revolutionized since the presumption based on the fact of seven years' unexplained absence was adopted. The presumption of death from absence can not have the strong probability of fact as its basis which formerly supported it, and persons who, for their own profit, assume the burden of establishing in courts of justice that the death of an individual has occurred have little excuse for urging their own isolated ignorance of his fate or his whereabouts as the principal item of their proof.

Power of Claim Agent to Employ Physician.

The Kansas City Court of Appeals affirms a judgment in favor of a physician, the plaintiff in the case of *Reynolds vs. C., B. & Q. R. Co.* It says that a passenger named Coffey was injured, May 20, 1902, in a wreck near Albany, Mo. The agent of the station caused him to be moved to a hotel in said town and sent for physicians to attend his injuries. About five days thereafter Coffey sent for the plaintiff, his family physician, to consult with the physicians already in attendance in reference to his treatment and removal to his home in King City. Previously, however, a stock agent of the railroad company had been to see Coffey and had consulted with the physicians in attendance, and had joined in the request of Coffey for the plaintiff for said consultation. The plaintiff treated Coffey for his injuries for about thirty days while he was at Albany, when he was removed to his home in King City, after which time he was his regular attending physician. On the 8th day of July one Wood, who claimed to have authority to adjust claims against the railroad company for personal injuries, saw Coffey at King City and made inquiries as to the kind of care he was receiving and the treatment that the plaintiff was administering to him. Wood saw Coffey more than once after he was moved to King City, at one of which times, when the question

came up who was to pay the plaintiff for his services, he said: "We pay all bills." At one time the plaintiff had a conversation with the station agent of the company at King City, in which he said to the agent that he was not satisfied with the progress made by Coffey and that he wished a consultation in the case. The agent referred him to Wood, and Wood came to King City. Coffey compromised his claim against the railroad company for \$2,500, but in so doing he did not include the medical bill of the plaintiff. At the time of the compromise the plaintiff was summoned to St. Joseph, where the compromise was consummated. He was sent for to confer with the company's general physician and surgeon and other physicians in reference to Coffey's injuries. Wood, for his services and expenses in that matter, as agent of the company, allowed and paid them. But in this case for services, as above stated, which resulted in a verdict in the plaintiff's favor for \$478, the railroad company contended that there was no evidence to show that Wood or any one else had authority to bind it for the payment of the plaintiff for his services so rendered. The court, however, says that the evidence here tended to show that said agent was acting within the scope of his authority when he employed and agreed to pay the plaintiff for his attendance on Coffey. The acts of said agent in visiting the injured, employing physicians and consulting with them in reference to their condition and treatment, taken in connection with the acts of the company in paying for the services of such physicians, was proper evidence to go to the jury, and was sufficient to support the finding that said Wood, when he employed and agreed to pay the plaintiff for his attendance on Coffey, was acting within the scope of his authority. The said Wood appeared to have been put forward as a general agent in looking after such persons, and was placed in a position where others were justified in the belief that his powers were general in that respect, and whatever restrictions there may have been imposed on said agent as between him and the railroad company could have no effect on the rights of third persons, who had no knowledge of the restrictions or limitations on his apparent authority. The court is of the opinion that, as agent of the railroad company to settle claims against it for personal injuries, he was within the scope of his authority in agreeing to pay the plaintiff for his services as physician for Coffey, and, as it was necessarily a part of the latter's claim for damages, it was immaterial whether this agreement to pay was made with the plaintiff or with Coffey, and it was also immaterial whether he employed the plaintiff to render the services in the first place.

February 17.

- 1 *Puerperal Infection. E. McDonald, New York.
- 2 *Congenital Malformations of the Heart. A. G. Ellis, Philadelphia.
- 3 *Cleansing of Milk Vessels: Relative Value of Washing Powders. A. H. Stewart, Philadelphia.
- 4 *Facts About Eczema. J. W. Achorn, Boston.
- 5 Typhoid Fever: How Can It Be Eliminated? J. L. Jefferson, Syracuse, N. Y.
- 6 *Abscess of Antrum Causing Symptoms of Acute Articular Rheumatism. K. K. Wheelock, Ft. Wayne, Ind.

1. **Puerperal Infection.**—McDonald reports six cases of which a careful study was made. She found that while streptococcus infection is usually the most common and severe type of infection, other organisms, which usually produce clinically mild symptoms, may produce a severe type of this disease with a fatal termination. She urges that the term puerperal infection should be broadened to include infection elsewhere than in the uterus, and that the location and nature of such lesions should be recognized before any operative measures are undertaken. The presence of pathogenic micro-organisms in the genital canal is by no means sufficient evidence on which to base a diagnosis of puerperal infection.

2. **Congenital Malformation of Heart.**—Anag 3,875 autopsies performed at the Philadelphia Hospital during the past

thirteen years Ellis found 46 cases of cardiac malformation. Four cases are described at length. One is a case of the rare condition of pectoral heart with divided sternum; the child was a full-term male and lived twenty-three and a half hours. A second case is one of transposition of the aorta and pulmonary artery, the child living thirty-four days. The third and fourth cases are instances of perforate interventricular septum and absence of anterior portion of auricular septum, respectively.

3. Cleansing of Milk Vessels.—Stewart commend a method which consists of washing the bottle and cans by a powerful stream of some hot washing powder solution with rapid solvent power pumped into the bottles, which are then rinsed with boiling water. This method cleanses 95 per cent. of the bottles perfectly. Stewart urges the establishment, under supervision of the bureau of health, of can-washing and cleansing buildings where all cans may be sterilized before they are sent to the farms. The advantages of such a scheme would be: 1. Saving of milk which is now destroyed by rapid fermentation due to infection from dirty cans; 2. saving of ice used to preserve milk which is eventually lost; 3. saving of time; 4. abolition of the use of preservatives; 5. saving of space for the storage of empty cans; 6. increased sale of milk due to restored confidence in its purity; 7. saving of the lives of thousands of children who are now fed on fermenting milk, the food value of which has been lost; 8. prevention of epidemics of dysentery and other milk-borne diseases.

4. Facts About Eating.—Achorn inclines to the belief that many conditions, such as arteriosclerosis, rheumatism, asthma, eczema, neuralgia, etc., are caused by overeating, by too much eating of one kind of food, by taking meals too close together, by nibbling between meals, by taking too much liquid during or immediately after eating, and by not chewing food sufficiently. No more food should be taken into the body than is required by the physiologic needs of the system.

6. Abscess of Antrum Causing Rheumatism.—Wheelock reports a case of pneumococcus infection of the antrum which was followed by general symptoms of acute articular rheumatism. The patient, a woman, had been suffering from a "cold in the head" with free discharge from the right nostril from the beginning of the attack. The frontal sinus was washed by means of a cannula, and on the following day she had a severe chill which was followed by rise in temperature and she was confined to her bed for twenty-four hours. Later she had severe pain in right knee, left elbow and shoulder. This pain and tenderness lasted about forty-eight hours. The second day following the chill the temperature was 100 F. From the first pus could be seen between the anterior end of the middle turbinate and the external wall of the right naris. Exploratory probe puncture was made and two teaspoonfuls of thick pus worked out, which showed pneumococci. Following the flushing of the antrum the naris was free from pus. Pain returned on the following day, when the antrum was again flushed and about one teaspoonful of pus brought away. Patient made a rapid recovery following the last lavage and regained the weight which she had lost during her illness.

- 8 Head Injuries. M. Prince, Boston.
- 9 *Indications for Operation in Head Injuries. W. N. Bullard, Boston.

7. Indications for Operative Treatment of Head Injuries.

As the result of an extensive personal experience with head injuries, Sachs has arrived at the conclusion that if there is an extensive injury to the skull, particularly in the parieto-temporal region, whether it be fracture or fissure; if there is evidence of splintering of the inner table, or of the presence of a foreign body or of persisting intracranial hemorrhage, operative interference is warranted at the earliest possible moment. (A ray examinations and lumbar puncture are valuable diagnostic aids.) In comminuted fracture of the skull the surgeon must decide whether or not the danger of infection is increased by surgical procedures. Surgical technique and surgical methods

should be developed to such a degree that the brain and skull will be handled with as much skill as are the abdominal viscera. In all cases, but especially in those in which external injury can not be considered the determining factor, the question of surgical interference must be decided on purely neurologic lines. Sachs does not approve of continuing the discussion of the differentiation between concussion, contusion and compression. He says that it is much more important to decide whether the brain has or has not been injured tangibly; and if injured, whether the site of the injury is on or near the surface; in short, whether or not it is accessible. If inaccessible, simple trephining may be resorted to, provided there are symptoms of increasing intracranial pressure which can not be relieved by lumbar puncture or by other simpler methods. Even if the injury is in an accessible region, it is best to adopt a conservative attitude and to determine whether we may trust to surgical skill rather than to the reparative powers of nature. Hemorrhages are often absorbed and many inflammatory processes recede more or less spontaneously. In determining the gravity of brain injury Sachs considers disturbances of cardiac and respiratory action, of vesical and rectal control, and the condition of consciousness as the most important symptoms. These are the manifestations of increasing intracranial pressure and of other serious injury. Recovery from coma, however slight, after twenty-four, forty-eight or seventy-two hours, is encouraging; deepening coma is of grave significance. The behavior of the pupillary reflexes is of no special value in deciding the question of operative interference. If the symptoms point to distinct focal lesion, although years may have elapsed since the initial injury, surgical measures must be adopted, providing only that the lesion be accessible. If the external injury points to one site and the symptoms to another, Sachs advises considering both, attacking the site of external injury first, but trying to reach the other as well.

9. Id.—In all cases of compound fracture of the external surface of the cranium in adults, Bullard advises immediate operation. In cases of simple fracture he considers it safer to operate in all cases in which there is clear external evidence of fracture, although in children it is sometime permissible not to operate when no symptoms exist. He also advises operating on all depressed fractures; in all cases in which symptoms of little meningeal hemorrhage exist; and when unconsciousness comes on after an interval of consciousness following injury to the head; in adults, whenever the unconsciousness after a severe injury lasts more than twelve hours, and when it is evident that the unconsciousness is due to the injury and not to other causes; when persistent unilateral convulsions follow injury to the head in an adult, provided that such convulsions never occurred previous to the injury and that no other cause for them exists. Inequality of the pupils occurring immediately or shortly after injury also is an indication for operation. Slow pulse, with other symptoms, is an indication for operation; rapidity of the pulse is not a contraindication, although weakness of the pulse may be.

10. Teacher's Part in the Tuberculosis Problem.—Knopf calls attention to some of the particular duties devolving on teachers in the struggle against this disease which so essentially attacks the masses. The pupils should be taught to love fresh air. Ventilation of class rooms should be ample. When the site of the schoolhouse does not permit of the possession of large playgrounds, a roof garden, which can be covered in winter, is absolutely necessary. Heating and general ventilation of these rooms should be of the most improved kind. The walls and woodwork of the school room should be plain and

easily cleansed. All corners should be rounded and the wall-painted. The school furniture should be so arranged that it can easily be moved so that the floors can be thoroughly cleansed after each daily session. The hygienic drinking fountain should replace the drinking cup. A well-equipped gymnasium and a swimming tank with constantly running water, suitably warmed, should be the property of every public school. Every pupil should be taught to swim and should be given the opportunity to bathe several times during the week. Knopf says that teachers may do more toward the prevention of tuberculosis by teaching the children under their charge how to breathe, sit, stand and walk properly than the entire number of physicians taken together can accomplish. He gives a number of rules which he advises teachers to have printed on leaflets to be read and reread by the pupils, and explained and commented on by the teacher. These rules include common methods of prevention of the transmission of tuberculosis and refer to such subjects as spitting, coughing, sneezing, cleanliness of finger nails, and so on. He calls attention to the proper feeding of school children, and advocates the offering of school lunches at moderate prices. He shows the great danger lurking in alcoholic drinks, including patent medicines, which are in such common use among the masses. An important point, he says, in the prevention of tuberculosis among school children is that the school teacher should be familiar with the subjective signs and symptoms of tuberculosis and the characteristics of the person disposed to consumption. He believes in weeding out the tuberculous child and the tuberculous teacher from the public schools, but he also believes that we should provide for these same patients, both teachers and children.

13. Non-Operative Treatment of Prostatic Hypertrophy.—Reynolds, while admitting the necessity in many cases, holds that the patient should not be urged to operation until proper systematic treatment has been tried. In catarrhal prostatitis he employs massage at sufficient intervals to free the glands and to relieve the congestion, unless contraindicated in cases in which interstitial changes have taken place in the prostatic tissues. All alcoholic drinks must be stopped, and a careful watch kept on the urine. He considers that the best remedy for relieving the congestion is nitrate of silver, the application to be made with a rubber catheter attached to a small syringe. The solutions should be mild at first and increased or decreased in strength according to the effect produced. If considered advisable for the patient to use the catheter himself definite instructions should be given him as to the manner of doing so, and the method of keeping it clean. He considers that in cases of this kind the patients may lead comfortable lives, well satisfied with their condition; so well satisfied, indeed, that operation will not be considered.

14. Factor in Perineal Lacerations.—Shippis explains why violent and uncontrolled expulsive efforts of the mother just prior to the birth of the child play an important part in the causation of perineal rupture. The patient is worn out with the exertion which she has been making for hours, and which she believes to have been futile. She is anxious to see the end of her sufferings, and, listening to the advice of her friends, she uses all her reserve force and strains with all the energy of which she is possessed. Shippis believes that too short a time is given, as a rule, for the physiologic softening and stretching of the tissues. In his practice he encourages the woman in labor, assuring her that though the pains she is suffering are apparently accomplishing little, they are in fact surely preparing the way for the birth of the child. He, moreover, warns her of the approach of the period just prior to the delivery, when all bearing-down efforts must cease. The integrity of the perineum remains intact in proportion as control over the last expulsive efforts of the patient is secured. Shippis operates in every case of laceration, except the most superficial.

15. Treatment of Cerebrospinal Meningitis.—According to Osborne, the treatment of this affection consists in diminishing congestion, in taking means to prevent or to relieve cerebral or spinal pressure, and in combating all acute symptoms and complications as they occur. He says that the administration of diphtheria antitoxin in cerebrospinal meningitis is theoretically unsound and practically a failure. Spinal puncture is indicated when there is cerebral pressure, but he is in doubt as to whether or not it is indicated for diagnostic purposes, except in rare instances. The almost constantly beginning sore throat should be treated with antiseptic gargles and sprays, none better, he thinks, than the hydrogen peroxid solution. Conjunctivitis should be treated with simple boric acid solution. A calomel or saline purge should be given, and painful joints should be wrapped with cotton and kept warm. Pain should be stopped with morphin, by the mouth or hypodermically, depending on the intensity. If the pain is not severe and there is no vomiting, and if the pulse is good, bromids or chloral may be administered for the first two or three days. To quiet cerebral excitement and delirium, and to intensify the action of the morphin which must be given, Osborne believes that there is nothing that will compare with ergot, given intramuscularly or subcutaneously. The frequency of its administration should be about once in six hours, unless there is great cerebral excitement or the pulse is bad. The ice-cap to the head and the spinal ice-bag are necessary. If the temperature is subnormal or the surface of the body is cold, dry hot applications are of advantage. The general care of the patient should be the same as in typhoid. Osborne is convinced that ice, ergot and morphin will save many patients from death from this disease. Alcohol, strychnin and quinin are contraindications, although the first two are permissible in an emergency.

18. Ossiculectomy Under Local Anesthesia.—Ballin believes that ossiculectomy may be performed in some chronic catarrhal conditions of the middle ear, especially when the hearing is greatly reduced, when the subjective noises are extremely annoying to the patient, and when all other means have failed. The operation is free from pain and is not accompanied by hemorrhage. The anesthetic used is a 1 per cent. solution of cocaine to which is added an equal part of a 1 to 1,000 adrenalin solution. Twenty to thirty minims are sufficient to bring about the desired anesthesia. The instruments used and the method of operating are described in detail.

24. Oration in Medicine.—Marvin states that in his opinion the supreme test of the medical man is his possession of the ability to recognize disease in the individual and to treat it properly. Test-tube experiments, he says, should never outweigh bedside testimony. He states that Koch's discovery of the etiology of tuberculosis was epoch making, and that when he announced the discovery of tuberculin the medical world was on the tiptoe of expectancy. Behring's diphtheria antitoxin was discovered shortly afterward and since then many

serums have been presented to the profession, and many theories concerning the solution of the problem of infectious diseases have led astray even the elect. Many of these claims, Marvin says, are an abomination to science and a menace to educational progress. More recently the study of chemical products has been assiduously pursued, though unfortunately there has appeared to be some antagonism between the biologist, chemist and the clinician. Much of our literature has been burdened with laboratory jargon meaning anything or nothing, according to the reader's opinion. The manufacturing druggist and the dealer in proprietary drugs pander to our inordinate gullibility, and by the use of the name and garb of easily-coined pseudo-science lead many willing captives by the witchery of their eloquence and make some physicians facile fabricators of fiction and others quasi-indorsers of crass misrepresentations of chemistry and science. If we trust "the true-seeming lie," all that is necessary to compel Nature, however crippled, to resume labor and build up tissue, is to administer any one of a number of predigested, peptonized, malted or otherwise fake foods or pretensions tissue-builders, claiming to be competent therapeutic foods without the intervention of digestive effort; or some chemical compound so nearly protoplasmic as to build tissue itself without Nature's co-operation or consent. The trend of medical research, Marvin believes, is along the line of pathology, but the clinician should follow closely in its wake. Care and exactness in diagnosis are of prime and fundamental importance. A diagnosis may be etiologic, clinical or pathologic—in other words, an opinion based on the specific cause of disease in an individual case. Etiology and pathology have been unduly magnified and therapeutics is in danger of being forgotten. It has been claimed, but not corroborated, he says, that the various serums represent an era of specific therapeutics, but we must still use some of the empiric remedies. The claim is made that by the use of some favorite intestinal antiseptic—the golden calf of the manufacturing pharmacist—typhoid fever may be aborted or its course shortened. If physicians would carry their pathology with their therapeutics to the bedside, and realize that typhoid fever is more often a general bacteremia than an intestinal disorder, and that in 80 per cent. of the cases the specific bacillus can be found in the blood, they would realize the absurdity of the claim that any of the so-called intestinal antiseptics can exert any appreciable influence over the twenty or more feet of intestine and the entire blood stream. Because glycerin is hygroscopic, it is but the counterfeit of science to claim that a paste of glycerin and fine clay applied hot to the chest will have any effect on a pneumonia, no matter how learnedly the manufacturing chemist may talk about osmosis. The injection of some fluid of unknown composition in tuberculosis smacks of quackery. A tyro in chemistry would laugh to scorn the claims about nascent chlorine and ozone. Water—the cheapest and commonest thing in Nature—is bottled, and the price of wine is paid for it, and we imagine it cures Bright's disease and diabetes. These are but examples of therapeutic optimism which needs to be shunned as much as therapeutic nihilism. In the treatment of disease the tendency is to over-treatment and meddlingness. In a disease that is self-limited and running generally a short course, the skill of the physician is taxed, and while prompt and energetic treatment may be necessary to save life, useless drugging and agencies applied internally, over-feeding and over-stimulation and over-handling or over-nursing are fraught with great danger. Fresh air, digestible food in small amounts, sleep—tired Nature's sweet restorer—and the treatment of symptoms as they arise are the beacon-lights in the management of this disease. The physician is the most misunderstood of men. Medicine is an art, a profession, and can not be judged by the standards of trade or business. If Nature be but evolution, mere cause and effect, she neither kills nor cures; she can be guided or misguided by the physician. In matters of life and health the physician utilizes or combats the forces of Nature. His best energies are always directed toward inhibiting the various conditions from which he gains his livelihood. He has no patents or trade secrets, no proprietorship in anything his colleague may not use for the benefit of humanity. He strives

to prevent disease, to perfect measures to alleviate suffering, and through his societies, the medical press and libraries open to the public, he teaches the layman how best to dispense with the services of the physician. The physician should be a public servant as well as the servant of the individual. He is the apostle of health and healthfulness. He is the conservator of peace and happiness of society, the trustee of the health of the community.

30. Operative Treatment of Cleft Palate.—Peck calls attention to certain points in technic which aid in securing prompt surgical closure of the cleft with a minimum amount of damage to the muscles of the soft palate. He believes that children of 6 or 7 years of age are the most favorable subjects for operation from the purely surgical standpoint. The very serious disadvantage is that habits of speech are already formed and the defect in pronunciation is more difficult to overcome. Peck invariably uses the hanging head, Rose position, intermittent ether anesthesia with an open cone, and the Whitehead gag. He never resorts to preliminary tracheotomy and does not believe that it should ever be necessary. The special instruments used are the Whitehead mouth-gag, a very slender knife for transfixing the edge of the flap, paring and splitting the edge of the uvula; a long, slender pair of mouse-tooth forceps; a strong, straight scalpel for making the lateral incisions; a thin, blunt periosteal elevator, slightly curved on the flat; a sharply curved Deschamps' handle-needle for passing the heavier sutures, and his own special needle-holder and needles for the fine sutures. The edges are pared by transfixing the edge of the soft palate with a very fine, sharp knife and cutting first forward to the anterior angle of the cleft, then backward, bringing the knife out at the base of the uvula; the strip removed should be as narrow as possible to avoid waste of tissue, but the full thickness of the flap. The mucous membrane of the uvula is then split on its inner border, i. e., facing the cleft; it easily separates to give a sufficient raw surface and all of the tissue of the rudimentary half of the uvula is saved. The denudation is repeated on the opposite side of the cleft. The lateral incisions are now made, commencing opposite the last molar tooth close to the border of the gums and carried forward to a point opposite the anterior extremity of the cleft, but taking great care to leave a broad anterior pedicle to the flap for nutrition. This incision falls external to the posterior palatine foramen and the main trunk of the artery as it runs forward; the branches are first divided, the main trunk being usually torn by the periosteal elevator. In clefts running forward through the alveolar process Peck prefers to leave the extreme anterior end of the cleft for later closure rather than endanger the nutrition of the flaps by prolongation of the lateral incision and narrowing of the pedicle. The curved periosteal elevator is then inserted in the lateral incision, and hugging the bone, is forced carefully through into the cleft; by lateral sweeps

the entire flap is quickly separated, including the mucoperiosteum at the anterior angle of incomplete clefts. Posteriorly the instrument is strongly carried outward and backward along the posterior margin of the hard palate, and to a great extent detaches the palatine aponeurosis and the mucous membrane on the nasal aspect of the velum from the bone. In the majority of cases hemorrhage soon ceases to be troublesome after this blunt separation; posterior branches of the descending palatine artery remain uninjured for nutrition of the posterior portion of the flap, even after very free separation with the raspatory. The inner edge of the flap is then seized with mouse-tooth forceps at the base of the soft palate, i. e., where the muscular pull concentrates, a thin, straight bistoury is inserted through the posterior part of the lateral incision, and cutting outward and backward as traction on the flap is made toward the median line, the detachment of nasal mucous membrane and palatine aponeurosis from the posterior border of the hard palate is completed, and by a careful sawing motion enough of the mucous membrane of the nasopharynx is divided to allow the edges of the flap to fall to the median line without tension. Few, if any, of the fibers of the bellies of the levator or tensor palati are cut. The palatine aponeurosis which receives the insertions of the tensor and levator is completely detached from the posterior border of the hard palate as far outward as the base of the hamular process, together with the mucous membrane on the nasal aspect of the soft palate, allowing the velum to drop downward. This aponeurosis with its muscular insertions remains in the flaps. In cases of wide cleft, tension on the flaps is still caused by the shortened salpingo-palatine fold of mucous membrane running upward and backward on the lateral wall of the pharynx along the belly of the levator palati. Peck says that free division of this fold by gently tearing with the finger or snipping with blunt curved scissors as traction is made on the flap downward and inward to make it prominent, is easily accomplished without damaging the muscles, and effectually relieves tension. All this can be done without unduly narrowing the bridge of tissue behind, or endangering the nutrition of the flap. By this time the hemorrhage has nearly ceased and the flaps are ready for suture. Beginning close to the base of the uvula, sutures of iron-dyed silk, No. 6, are passed on the Deschamps' handle needle through the entire thickness of both flaps at a sufficient distance from the edge to guard against cutting through; these are left untied until the last is passed, four or five being usually sufficient, placed from one-fourth to one-third of an inch apart. They are then tied in order, with a surgeon's knot, usually beginning with the posterior stitch, the ends being left long for the time. Intermediate stitches of iron-dyed silk, No. 3, are then placed between each of the heavier stitches, and two or three in the uvula itself, the last at its tip or even on the nasal aspect. They are passed on the very fine special needles with the eye in the point, carried on the special needle-holder; they include only part of the thickness of the flap, are closer to the edge, are tied immediately and insure accurate apposition of the edges, such as is aimed at in all fine plastic work. Five to seven of these are used, making in all ten or twelve sutures. The long ends of the heavier sutures are used for traction and steadying the flaps during the passage of the fine sutures, especially in bringing the uvula forward. Each, as it has served its purpose, is cut short. In the treatment of the lateral incisions Peck uses a device suggested by C. H. Mayo; a piece of white tape is passed around both flaps through the lateral incisions, drawn just tight enough to approximate the flaps slightly and guard against tension, and secured by a silk ligature. The ends are cut short and slip around to the nasal surface of the flaps. This is left in place seven days and serves for drainage as well as for the relief of tension.

35. *Value of Duodenocholedochotomy.*—Hancock states that in favor of duodenocholedochotomy for gallstones in the lower end of the common duct are: (a) the avoidance of drainage some cases in which one would not otherwise wish to sew up the wound in the duct and close the abdomen; (b) the greater ease in sewing the duodenal than the duct incision by virtue of size and proximity of the former; (c) uniformly kindly

healing of intestinal wounds; (d) easy and natural access to common duct; (e) ease and benefit of dilatation of papillary orifice in insuring better drainage of bile and detritus.* (1) duct may be safely incised for half an inch in extracting stone or in enlarging the orifice for drainage. Against the procedure has been raised the common prejudice against opening the gut in general, the fear of fistula which occurred in but two out of 62 cases, and the dread of infection which, as indicated above, has been vastly overated in regard to the upper half of the intestines. In neoplasm of the papilla this route is clearly indicated for diagnosis and treatment when the growth is amenable to local treatment and the gall bladder can not be used for anastomosis or drainage. In total stenosis of the papillary orifice, whether from neoplasm or trauma of stones, a choledochoduodenostomy could be done with the incision employed in duodenocholedochotomy, where the anastomosis could be made low down in the common duct. In pancreatic stone a duodeno-pancreo-lithotomy is an established procedure and for good anatomic reason is the method of election.

37. *Anomaly of Duodenum.*—Mumford cites the case of a young man who had suffered severely with gastric symptoms for five years. It was obvious that he had a greatly dilated stomach. An immovable mass about the size of a pigeon's egg could be felt in what was thought to be the pyloric region. It was assumed that this mass was of inflammatory origin and a drainage operation was advised. On opening the abdomen Mumford found that a large part of the pyloric portion of the stomach was greatly thickened, and was held up to the liver by strong and dense adhesions. On turning up the omentum, colon and stomach and searching for the jejunum, Mumford found that that portion of the gut did not spring from the ligament of Treitz on the left crus of the diaphragm, but from the right crus. In other words, the fixed duodenum ended on the right of the spinal column. Little was thought of this anomaly at the time. A short-loop posterior gastroenterostomy was done, the opening in the stomach being made as near the pylorus as possible, and the opening in the jejunum about three inches from the ligament of Treitz. All went well until the fifth day after the operation, when the patient complained of some epigastric uneasiness. Later in the same day he underwent a sudden and violent paroxysm of severe abdominal pain, associated with profound and alarming collapse. Death ensued on the sixth day. The autopsy disclosed the abdominal cavity flooded with gastric contents. A large rent was found in the fundus of the stomach.

39. *Transverse Incision in Appendectomy.*—Davis employs two incisions, each being designed to avoid wound arteries, and to make the appendix easily accessible. For easy cases the incision is made directly transverse, one and a half inches long. Its center is to be on the semilunar line on a level with the anterior superior spine. The aponeurosis of the external oblique is divided in the line of the skin incision, but obliquely to the direction of its fibers. The fibers of the internal oblique and transversalis muscles are parted—not cut—in the same line as the structures above. The peritoneum is then opened and the incision carried inward through first the anterior layer of sheath of the rectus. A blunt retractor three-quarters of an inch wide is then inserted and the muscle drawn toward the median line. This exposes the transversalis fascia and peritoneum posteriorly which are then also divided. Thus is obtained a triangular opening with its base of three-quarters of an inch and two sides of about an inch long, which is ample for simple cases. If the case is a difficult one, the outer end of the incision is prolonged to the anterior spine or even above and inwardly through the sheath of the rectus to within an inch of the median line. This will give an opening from four to five inches long, according to the size of the patient, sufficiently large to insert the hand if necessary, and through which the appendix can be extracted under almost all circumstances. In cases in which drainage is necessary, the drain is brought out at the angle of the wound and lies close to the bony anterior superior spine and passes through the thick muscular mass of the internal oblique and transversalis, all of which insures against the formation of a hernia at that point. The inner portion of the wound is protected absolutely

against hernia by the rectus muscle, and to its outside there are the thick internal oblique and transversalis muscles beneath, and above them the aponeurosis of the external oblique. Davis says that the division of the external oblique aponeurosis obliquely instead of parallel to the direction of its fibers may be urged as an objection, but this is more than compensated for by the better access which is afforded. No hernias have come under his observation even in suppurative cases.

41. Radical Cur of Severe Femoral and Inguinal Hernia.—The method of operating described by Nicoll is applicable to both femoral and inguinal hernia. Its main features are: (a) the employment of the sac to form an intra-abdominal buttress over the internal aspect of the hernial opening or ring; (b) the use of the pubic ramus as a *point d'appui* in the process of closure of the hernial canal, and (c) the additional security of closure obtained by the superposition on the bone sutures of a plane of fascial sutures. The technic of the operation is as follows: Obliteration of the sac, also of the peritoneal depression over the abdominal aspect of the ring, and the substitution of a buttress over the internal aspect of the ring. The sac is exposed and cleared from surrounding tissues (the skin incision may be vertical or transverse). It is then opened longitudinally in its middle line, cleared of its contents, and separated from parts surrounding its neck, including the transversalis and the iliac fascia, for one inch round the abdominal aspect of the ring. Next, the sac is bisected longitudinally from fundus to neck, and an aperture is made in one half near the neck, and the halves are interlocked by putting the other through the aperture. In certain cases it lies better if previously twisted one-half turn on its longitudinal axis. Next, the whole sac is reduced through the femoral ring into the extraperitoneal space previously cleared for it by detaching its neck from the abdominal aspect of the ring. The sac thus lies bunched up within the abdomen, between the peritoneum and the transversalis and iliac fascia over the internal aperture of the femoral canal. When the sac is unnecessarily large part of it may be cut away before reducing it through the canal. An incision is carried (bone deep) from the femoral vein along the pubic ramus to the region of the pubic spine. This divides the pubic portion of the fascia lata, the origin of the pectineus, and the periosteum. Its length depends on the extent to which the femoral vein has been displaced outward by the presence of the hernia. The periosteum is then detached to a limited extent and retracted. The bone is drilled near its upper edge in two places, from one-half inch to one inch apart (one drillhole may be made to suffice). Through one of the apertures a loop of stout catgut or other absorbable ligature is passed, either by threading it in the eye of a curved surgical needle, or by pushing it through, simply doubled on itself. It is, however, more easily passed by threading it in the eye of the bone drill or in the eye of an ordinary surgical probe. For the purpose Nicoll employs a special probe in which the eye is small and placed very near the extremity of the handle. The loop of ligature is divided and one end is threaded in a large curved surgical needle and passed as a mattress suture through Poupart's ligament. Unthread it from the needle, repeat this with the second end, carrying it through Poupart's ligament at a higher level, avoiding the deep epigastric artery to the outer side, and, in male patients, the spermatic cord above. By means of the probe (into the eye of which the ends are threaded), both ligatures are withdrawn through the second drillhole in the bone. The ends of each loop are tied separately over the front of the bone, thus bringing Poupart's ligament down to the postero-superior surface of the bone and fixing it firmly in contact with that surface, constituting what is in effect an extension outward of Gimbernat's ligament, and absolutely closing the femoral ring to whatever extent may be desired, due regard being paid to the amenity of the femoral vein. The degree of occlusion is regulated by the position of the sutures in Poupart's ligament, but not by the tension with which they are tied. This latter does not vary, the knots being tied in all cases firmly to bring the ligament into contact with the bone. To make the closure doubly secure the operation is completed by uniting, by interrupted catgut sutures, the detached margin of the pectineal origin and the

pubic portion of the fascia lata to the "anchored" Poupart's ligament.

42. Radical Operation for Inguinal Hernia.—Eastman has devised a method for introducing a single tier of non-absorbable sutures which coapt all the layers either according to Ferguson's or Bassini's methods. These sutures may be removed easily after firm union has taken place. In 11 cases Eastman has used heavy Pagenstecher celloidin linen. The manner of introduction of the sutures is simple. After incision down to the aponeurosis of the external oblique, exposing both rings, the overlying superficial tissues should be wiped with gauze from the aponeurotic layer to such an extent that Poupart's ligament may be freely exposed. After reduction of its contents the sac should be twisted on itself, as practiced by C. H. Mayo, so that all the slack of the peritoneum about the neck of the sac may be taken up before the transfixing suture is introduced. The Pagenstecher linen suture, bearing a needle on each end, is first passed through Poupart's ligament from without inward one inch from its free margin. It is then passed through the outer border of the internal oblique and transversalis muscles and brought back through Poupart's ligament about one-third of an inch nearer the margin of this ligament than its first point of passage. The needle, now external to and above Poupart's ligament, is made to overlap the free margins of Poupart's ligament and the aponeurosis of the external oblique by carrying the linen through in the form of a simple running mattress suture. The needle is next passed through the superficial fascia, panniculus adiposus and skin, emerging about one-eighth of an inch from the skin-wound margin on the side opposite Poupart's ligament. The needle on the tail end of the suture is brought up through the subcutaneous fat and skin on the side of Poupart's ligament. When traction is made on the two ends of the suture no kinks or curls remain, and the suture is tied up as a simple loop and, being clipped, may be drawn out with the slightest traction.

- 46. Surgical Technic. C. P. Thomas, Spokane, Wash.

45. Fracture of the Clavicle.—King has employed a number of dressings for fractured clavicle and finding none of them quite satisfactory, he now applies the following in most of his cases: Having removed the clothing from the chest, he applies a zinc oxid strip, of length and width suitable to the patient's size, placing the initial end at the inferior angle of the scapula, running it upward and outward over the top of the shoulder on the affected side, down under the axilla and then transversely across the back around the body to the midsternal line. The object of this strip is to fix the scapula, which King regards as the most important point in any method of dressing. Then he puts on a second strip, beginning at the free border of the ribs anteriorly, running it up over the tilted end of the inner fragment and down the back to several inches below the scapula. This assists in overcoming the pull of the sternomastoid. In suitable cases, when the patient is lean in flesh, small, tightly wadded rolls of cotton may be placed in the supraclavicular and infraclavicular fossae before this second strip is applied; they will act as splints to the clavicle. Pads in the axilla, large and hard enough to overcome the inward pull of the pectorales and scapular muscles, can seldom be borne on account of pain and pressure symptoms; however, a small pad of gauze and cotton is useful in absorbing sweat and odor. A snugly fitting undergarment may now be put on. The dressing is completed by placing the hand and arm in proper position and applying a snugly fitting Velpeau bandage.

- 17. *Annual Medical Progress Number.

47. Annual Progress Number.—For several years it has been the custom of this journal to review the progress made in medicine during the preceding year. The present issue con-

sists of 216 pages. The department of internal medicine, conducted by Dr. J. S. Myer, is devoted entirely to a consideration of some of the recent literature on diseases of the stomach. Dr. W. Bartlett, in charge of the department of surgery, devotes considerable space to physiologic surgery. Dr. A. E. Taussig discusses the contributions to laboratory diagnosis, particularly the methods dealing with the diagnosis of gastrointestinal affections. Dr. W. Baumgarten, in charge of the department of therapeutics, reviews the advances made in serum therapy and roentgenotherapy, and also mentions the agitation against the evil of nostrum vending. The departments of pediatrics, pathology and bacteriology and obstetrics and gynecology, orthopedics, neurology and psychiatry, genitourinary surgery, laryngology and otology, dermatology and syphilis, and ophthalmology are also well taken care of by those in charge, making this issue a most valuable one for those who wish to know of the progress made in all departments of medicine.

50. Effect of Temperature on Viscosity of Living Blood.—To solve the question of whether or not it is possible to alter the viscosity of the circulating blood by changing the temperature of the surrounding medium, Burton-Opitz performed a series of experiments on dogs in accordance with the method described by Huertl. Six experiments in all were made, three with warm (44 C.) and three with cold water (23 C.). The experiments proved conclusively that the viscosity of the blood reacts very sharply to changes in the temperature of the surrounding medium. The viscosity is decreased by warm and increased by cold water baths. Warm water baths also produced a decrease and cold water baths an increase in the specific gravity of the blood. On the other hand, it was found that hot air baths render the blood more viscous and that they also increase the specific gravity of the blood, just the opposite of the result obtained with warm or cold water.

51. Experimental Cirrhosis of the Liver.—The experiments performed by Pearce demonstrated that the reparative process which follows the widespread necrosis of the dog's liver caused by the injection of hemagglutinating serum constitutes a chronic interstitial hepatitis of definite and constant character. This is not only a new type of experimental hepatic lesion, but is more definitely a cirrhosis than is any other experimental lesion hitherto described. It is of importance in explaining the histogenesis of cirrhosis, and incidentally various repair processes in the liver, but it does not aid in the elucidation of the etiology of cirrhosis in man, nor does it explain the peculiar arrangement of the new connective tissue in any form of human cirrhosis, except, possibly, that associated with chronic passive congestion. It definitely demonstrates, however, that cirrhosis may follow extensive primary destructive lesions, a view not yet fully accepted, and supports the contention of Kretz that cirrhosis is essentially a reparative process.

- 8 Does Diachylon Affect the Infant When It Fails to Produce Abortion? R. Heelis, F. H. Jacob and S. R. Trotman.

2. When to Operate for Cleft Palate.—Murray prefers, as a general rule, to postpone operating on the palate until the child is between 2 and 3 years of age, and then to close the cleft completely at one operation. At that age there is more tissue to work with and it is generally possible to fashion a good, soft palate and uvula by paring the edges of the cleft and uniting them in the middle line. Excess of cicatricial tissue is thus obviated, for union takes place by first intention. The powers of articulation also are improved.

3. Closure of Gaps in Skull.—Pringle favors filling gaps in the skull with celluloid plates after the method devised by Fraenkel. Of six patients so treated, three operations were successful and two failed, the plate requiring to be removed because of sepsis. The sixth patient had two plates inserted; one healed in well and the other had to be removed because of

sepsis extending from the nasal cavity. Of the three successful cases, one patient has worn the plate for eight years, and the remaining two patients have worn theirs for more than three and a half years.

5. **Indications for Operation in Suppurative Middle Ear Disease.**—The objective signs mentioned by Syme as indications for operation are: 1. Pain on pressure over the mastoid, or more particularly over the antrum. This may or may not be accompanied by postauricular swelling. 2. A sinus behind the ear leading to an erosion in the bone. 3. Caries of the petrous bone. 4. An extensive or recurring growth of granulation tissue, pointing to invasion of the bone. 5. Facial paralysis. 6. The presence of thick, cheesy masses in the tympanic cavity, the inference being that the same condition exists in the antrum. 7. Very foul smelling discharge. 8. Stenosis of the meatus, either membranous or bony, either or both of which may be due to the irritation caused by the purulent discharge. 9. Persistent discharge in spite of regular and thorough antiseptic treatment. The subjective phenomena to be considered with regard to the advisability of or the necessity for operation are pain, vertigo, change in the hearing, and all symptoms which point to the impending onset or to the actual consummation of an intracranial infection. Syme says that in the larger proportion of cases of chronic otorrhea the patients do not show, at the time they present themselves for treatment, any of these indications. In such cases the ordinary antiseptic treatment with, if necessary, the rectification of an intranasal or pharyngeal condition, or in certain cases ossiculectomy, should be given a trial. If these measures do not affect a cessation of the disease within a reasonable time, its continuance should then be taken as a strong indication for radical operation.

- 17 *Dermoid Tumor of the Mediastinum in a Child Aged Two Years. G. Carpenter.
- 18 Uniform Lineal Growth of the Human Fetus. R. C. Roberts.

10. **Placenta Prævia.**—Warren reports a series of 94 cases in which six mothers died, or 6.3 per cent., while of 93 infants 49 died, or 52 per cent. As regards parity, of the 76 cases in which it is mentioned 12 were primipara whilst 36 had had five labors or more previously. None of the primipara died, which is a matter of some interest, since King in his series showed the mortality of primiparae to be 30 per cent., the general mortality in his collection being 22 per cent. Twin labors occurred twice in the series, of which three infants and one mother died. Recurrence in one case is noted in the three preceding labors. Hydramnios was reported in 4 cases, 2 of these being of the 10 cases seen personally. Prolapse of the cord happened in 3 cases out of 54 in which the de Ribes bag was not used, and in 4 cases out of 40 in which it was used. Postpartum flooding was noted in 14 cases, in 4 of which the placenta was adherent; adherence of the placenta was found in 2 other cases without postpartum hemorrhage. There seems to be a peculiar tendency for a placenta with a low implantation to become adherent. In 2 cases of postpartum hemorrhage there was atony of the uterus; both died. One case of puerperal melancholia is recorded. In one group of 27 cases only such minor steps as rupturing the membranes or giving ergot were taken. There was no case of complete placenta prævia in the group. In 6 other cases bipolar version was the treatment adopted. Twenty-one patients were treated by internal version or manual delivery in the case of pelvic presentations. Of the 21 mothers 5 died, and of the 22 children 14 died. Forty patients were treated by the insertion of the de Ribes bag. None of the mothers died; 25 of the infants died.

11. **Treatment of Heart Failure in Diphtheria.**—Bolton speaks of the value of the early administration of antitoxin in sufficiently large doses as a preventive of heart failure.

12. **Eucalyptus Oil in Ankylostomiasis.**—Phillips' plan of treatment is as follows: About 6 p. m. the patient takes a saline purge and then fasts all night. On the next morning he takes half of the following mixture, taking the remaining half an hour later:

R. Olei eucalypti	3ss	2
Chloroformi	gtt. xlv	3
Olei ricini	3x	40

In young boys and in feeble anemic patients the dose is divided into thirds and given at twenty-minute intervals. The dose can be repeated every second day. In 44 cases of ankylostomiasis the treatment was wholly successful. In 21 cases a single dose was sufficient, and in 16 cases two administrations were necessary. Phillips is convinced that the treatment is satisfactory with reference to its vermifuge effects.

17. **Dermoid Tumor of Mediastinum.**—Carpenter reports a case of this nature which occurred in a female child 2 years old. About a year before he first saw her she became languid, contracted a cough and subsequently developed pneumonia. At this time the chest was noticed to be bulging. She could not lie down, her respirations were accelerated, and she complained of pain in her side. When admitted to the hospital she was cyanosed and there was sucking-in of the lower intercostal spaces, mostly on the left side. The right side of the chest, in front, was dull from apex to base. On the left side, in front, there were dullness and tubular breathing above and below the clavicle. On the right side, behind, the chest was absolutely dull. The liver was displaced downward and there was a distinct depression between the liver and the costal margin. The radiograph which was taken at that time showed that the whole of the right side was opaque to the rays. The child died shortly afterward, and a postmortem examination was made. In front of the right lung was a mass the size of a fist. On incising this from six to eight ounces of clear fluid escaped. Inside the cyst was some cheesy material with a few hairs lying at the bottom. The rest of the tumor felt hard, although it consisted of a considerable number of cysts, most of which contained a gelatinous material of a light brownish color.

- 27 *Fibroid Tumor of the Vagina. G. F. B. Simpson.

20. **Sterilization of Hands.**—The results of experiments have convinced Stoney that it is possible to render the hands sterile or at least free from pathogenic bacteria by a simple and short method which does not require more than ten minutes. Therefore, the wearing of gloves during the performance of an aseptic operation is not necessary, though Stoney thinks it is advisable in the case of those operators whose skin is either unusually difficult to sterilize or easily injured by the constant use of antiseptics. The method employed by Stoney is as follows: 1, Scrubbing with a sterilized nail brush in hot water (as hot as can be borne) with carbolie soap for five minutes, several changes of water being used; 2, rubbing thoroughly with sterile gauze wet with methylated spirit; 3, immersion for one minute in a watery solution of biniodid of mercury (1 to 1,500). In every case the hands, instruments, silk, etc., were rinsed in sterile water in order to remove any excess of antiseptic which might interfere with the growth of organisms in the culture tubes. In all cases the hands were tested while wet and sufficient force was used both with the silk ligatures and scraper to remove a visible amount of epithelial debris.

21. **Foreign Bodies in Uterus.**—The foreign body in the uterus in the case reported by Helliér was an ordinary hairpin which the patient had introduced into the uterus. One point of the pin projected from the middle of the posterior lip of the uterus just above the surface of the mucous membrane, and

the other point could be felt under the mucous membrane at the junction of the cervix to the posterior vaginal wall. Removal was accomplished by drawing down the uterus, exposing the posterior prong with a snip of the scissors, then drawing down both prongs as far as they would come, and straightening out the pin, after which it was easily withdrawn.

27. Fibroid Tumor of Vagina.—The tumor in the case reported by Simpson measured $5\frac{1}{4}$ inches round the circumference, 2 inches longitudinally, $1\frac{3}{4}$ inches transversely, was tense in consistence, and not tender on pressure. The mass was covered by mucous membrane, which had become eroded at one point, leaving a round grayish area the size of a sixpence, and coated with a greenish-yellow secretion. The tumor was attached by a broad base, and springing from the left wall of the vagina just within the ostium vaginae, and growing distinctly outward. The left tumor was free from all sides of the vagina except the left, and the examining finger could be passed into the vagina beyond it more easily above and to the right of the swelling. The mucous membrane covering the tumor was incised vertically and dissected off backward, until access was obtained to the attachment of the tumor, which was discovered to be occupying the left lateral aspect of the vagina. On microscopic examination the main mass of the tumor was found to consist of fibrous tissue, more or less intermixed with plain muscle fibers. In some places the fibrous tissue predominated, in others the muscle cells were more numerous. On the whole, the two elements, fibrous and muscular, were fairly equally mixed, with perhaps a slight predominance of fibrous tissue.

36. Nasopharynx in Tuberculosis. Bourgeois and Ducos discuss what they call "pseudoatrophy coryza" in the tuberculosis. It was found constantly in the advanced and very frequently in the incipient cases. Ducos is inclined to regard it as part of the general predisposition to tuberculosis, and urges the necessity for treating and curing it, especially in the incipient stages of tuberculosis.

38. Syphilis and Myopia. De Laperonne thinks that myopia, whatever its degree and whatever the age of the patient,

should always suggest the necessity for a general examination. It is not enough to prescribe the proper glasses. The general condition should be examined and also the past record of infections, especially syphilis, inherited or acquired. If a myopic adult contracts syphilis, the usual precautions should be doubled. Not only should mercurial treatment be energetic and systematic, but the greatest attention should be paid to the myopia, with instructions to rest the eyes frequently. He has witnessed cases of detachment of the retina in myopic syphilitics. In one instance a lad belonging to a myopic family contracted syphilis at 17, and a year later had complete detachment of the retina in the left eye. He attributed this to a traumatism, but two or three years afterward there was partial detachment of the retina in the other eye. Considerable improvement occurred under intravenous injections of mercury cyanid, but the field of vision is still much restricted. In another case a myopic young physician, member of a myopic family, noticed impairment of vision seven years after contracting syphilis. The disturbances all vanished under energetic mercurial treatment, but three years later a large central scotoma developed in the left eye, due to hemorrhage into the macula. Atrophy of chorioiditis and circum-papillary chorioretinitis are affections common in acquired syphilis, like interstitial keratitis and progressive myopia in the inherited form. The progressive myopia noted in some cases of inherited syphilis is refractory to correction by glasses, even although the disturbances in vision do not indicate a high amount of myopia, not more than 10 or 14 D. In central choroiditis there may be a more or less extensive relative scotoma. This may aid in differentiating and in the prognosis. This pathological myopia was found more frequent among the illiterate in Tscherning's investigations, showing that school work can not be incriminated in these cases.

47. Albuminuria of Pregnancy.—Besides the albuminuria of a pregnant woman affected with Bright's disease and the albuminuria due to compression of the kidney by the pregnant uterus, there is another variety which Wallich calls "albuminuria from suppurative." The symptoms are polyuria with or without disturbances in micturition, and turbid or purulent urine, but very little general disturbance, no edema nor eye symptoms nor pain in the epigastrium. In the space of two months, recently, he noted this form of albuminuria in 6 out of 15 pregnant women showing albuminuria. He put these patients on a milk diet and administered methylene blue or other disinfectant for the urinary passages. The albuminuria may vanish, while the polyuria and turbid urine may persist, although without fever or other complications at any time during pregnancy and the puerperium. The main point is to decide whether the urinary apparatus is permanently affected; as a rule it is not.

54. Spermatic Insufficiency and Diastematic Insufficiency.—Ancel and Bouin explain that insufficiency of the testicles does not mean inadequate production of the seminal secretion alone. There is a seminal gland in the testicle and an interstitial gland. The seminal gland comprises the seminiferous tubules, while the intertubular connective tissue is what the authors call the interstitial gland or diastema. The latter is probably the seat of the production of the internal secretion of the testicles. Experiments on animals have shown that each gland is practically independent of the other and may fail in its task without compromising the functional activity of the other. There is, therefore, a "spermatie insufficiency" and a "diastematic insufficiency." The former is shown solely by the absence of spermatozoa and is physiologic in the aged. The diastematic insufficiency is manifested in other and numerous ways. If the gland fails to work at all, the age of puberty does not bring virility and the individual grows into a natural eunuch. If the gland does not fail until after puberty, the manifestations are less marked, but the beard and hair are liable to drop out, the voice to become hoarse, the mammae may develop and the outlines become more rounded generally. The individual may remain infantile or develop into a giant or present the characteristics of the female. These various types and transitions have been noted among pigs, and when slaughtered the testicles were found abnormal, as anticipated. Experiments on rabbits proved that it is possible to retard the

development of puberty for six months by ligating the vas deferens. Diastematic insufficiency in boys as puberty approaches is evidenced by a rapid and exaggerated growth of the limbs, tardy appearance of the hairy system and of the development of the external genitals, marked muscular weakness, nervous exhaustion, asthenopia, etc. The noticeable action of the interstitial gland in the testicle on the development of the skeleton is responsible for the stimulation of the growth of the epiphyseal cartilages as the first manifestation of diastematic insufficiency, transient or permanent, appearing during the period of puberty. They add that such lads seem to be peculiarly predisposed to tuberculosis, possibly owing to lack of the "invigoration" from the internal secretion of the interstitial gland in the testicle.

56. Inheritance of Tuberculosis.—Bossi's article is a contribution from an obstetrician to our knowledge of tuberculosis. He examined large numbers of placenta and of fetuses from women with tuberculosis, supplementing his research by experimental work. He found that it was a very rare exception when the Koch bacillus was transmitted to the fetus from the parents during its intrauterine existence. The toxins of tuberculosis may be transmitted. They seem to accumulate in the placenta and to pass thence into the fetus. The toxins thus transmitted are responsible for the defective development and organic weakness noted in such children. They favor infection during early infancy.

59. Pathogenesis of Eclampsia.—Semb writes from Christiana to describe extensive experimental experience in regard to immunization of rabbits against eclampsia.

64. Enteroposis.—Mathes remarks that the large number of women with enteroposis observed at the gynecologic clinic at Graz, where he is assistant, early attracted his attention, and he has made a special study of this condition. His conclusions may be summarized in the statement that enteroposis is a constitutional and hereditary anomaly of the entire organism, a lack of vital energy in all the body tissues, although it derives its name from the most striking manifestation, the sliding down of the bowels. The abdominal organs slide downward on account of the insufficiency of the frequently hypoplastic, sunken-in thorax and the relaxation of the abdominal walls. The organs in the lower abdomen thus become supported only by their ligaments and the abdominal walls. The condition is readily recognized from the general aspect of the body. The spine is bent over and the longitudinal axis of the thorax forms an obtuse angle with the similar axis of the abdomen. The expression of the face is juvenile. In short, the habitus enteropositis is identical with what we call the habitus phthisicus. The clinical importance of the anomaly depends on the degree in which the nervous system is involved. The greater the congenital anomaly, the earlier the results become manifest. This is especially the case in the infantile form characterized by hypoplasia of the thorax and the infantile general aspect. The chlorosis of such girls is a "crisis" of enteroposis. The latent predisposition is fanned into an actual malady by some special stress, some genital or other affection, an exhausting disease, pregnancy, tight lacing, overstrain, lack of proper nourishment or similar drag on the vitality. The symptom-complex of retroflexion of the uterus is identical with that of wandering kidney and enteroposis. The peritoneum of women with this displacement of the bowels is exceptionally sensitive, and this

sensitiveness is increased by any genital affection. The effect on the general nervous system has nothing to do with hysteria and neurasthenia. Enteroposis is undoubtedly on the increase, but the paintings of the old masters show that it has always existed. Memling's "Eve," in the Vienna gallery, is a typical example, and also some of Botticelli's women, while the number of modern painters who admire the enteroposic type, he states, is considerable, especially the pre-Raphaelites. Treatment must consist in general strengthening measures. In severe cases strict bed rest and Weir Mitchell forced feeding may be ordered. Gymnastic exercises to strengthen the muscles of the thorax and of the abdominal walls correspond to causal indications. A well-fitting abdominal bandage below the umbilicus, supported on the pelvic girdle, will put an end to a number of the disturbances. Weight from the shoulders should be avoided. In conclusion Mathes declares that the local treatment of gynecologic affections should be restricted to the minimum and to those cases alone in which it responds to the causal indications. Prophylaxis is important to recognize and to compensate the constitutional defect and to keep all exciting causes away from those predisposed to this condition. He denies the correctness of Hürmann's conclusions, mentioned in these columns on page 292 of the last volume, showing the fallacy of some of his premises.

66. Anatomic Findings in Progressive Deafness.—Brühl insists on the importance of functional tests of the hearing as a means of distinguishing between the various pathologic anatomic conditions underlying progressive deafness. It is possible to distinguish three groups by the functional tests, even when the membrane is intact and the symptoms are vague: the cases of progressive deafness in which the functional disturbances are due to an isolated affection of the middle ear, those in which it is due to affections of the internal ear and those in which both middle and internal ear are involved. He describes some of the functional tests and the mechanism of their action.

67. Modified Version.—Apfelstedt suggests that one of the arms should be drawn out whenever version by the foot is necessary. This imitates a natural process and prevents suffocation of the child in freeing the arms later. He advocates the measure for trial in the clinic, not for general adoption as yet.

68. Congestive Hyperemia for Acute Inflammations.—Stich reports 150 cases of acute inflammation at Garré's clinic treated by artificially induced hyperemia. The results have shown the harmlessness of the constriction used for the purpose, with proper technique, closely supervised, and they have shown again the constant relief from pain and the possibility of avoiding the necessity for mutilating operations. He relates the history of a case in which the constriction was applied without due medical supervision, with the consequence that the arm became permanently contracted, with chronic edema and inability to use the fingers, not from necrosis of the tendons, but solely from the excessive and overlong application of the constriction. In conclusion he emphasizes the fact that treatment with congestive hyperemia requires much closer medical supervision than any other method of treating acute inflammations. Physicians who have not the time, the patience or the opportunity for such close supervision should not attempt to treat a

patient by congestive hyperemia, as they are liable to do more harm than with the knife. If the physician has patience enough he should commence with mild cases and suspend the treatment if he does not succeed in banishing the pain, applying it again to the next appropriate case. By this tentative use of the new method he will soon gain confidence and enable his patients to profit by what Stich calls "this fruit of Bier's genius." The finest results are obtained with tendon sheath inflammations. The pain is relieved, the process aborted or shortened, and complete functional restitution is the rule. When the congestive hyperemia was induced with a suction cup fitting over the lesion into sound tissue around, as in case of furuncles or carbuncles, the pain subsided and the lesion healed after from two to ten applications, sooner than with other technics. In 50 cases the measure failed in only 3 instances. In the severer cases of osteomyelitis the results were less satisfactory. One of the 2 patients with acute arthritis was a physician suffering intensely from inflammation of the elbow and of the articulation between the atlas and the occipital bone, the result of gonorrheal infection five weeks previously. He was skeptical in regard to the congestive hyperemia, but the prompt relief of his pain soon converted him and his auto-observation proved instructive, as he reacted to the slightest blunder in technic. It was remarked in his case that the constriction of the arm and neck had to be a little tighter when he was reclining than when he was sitting up to obtain the same results. The articulations involved healed without the least impairment of function.

70. Detachment of Retina Cured for 23 Years.—Cohn describes the case of a patient with detachment of the retina who has been under observation for twenty-three years. The man was treated with sclerotomy twice repeated, the cure thus obtained persisting unchanged for seventeen years to date. He discusses the various methods of treating detachment of the retina, preaching always, "Everything out, never anything into the eye." Puncture of the sclerotic with the Graefe knife is the most promising measure, he says. He has performed sclerotomy 39 times, frequently with excellent results. In one case a girl was cured by darkness, revulsion and leeches without operative intervention, the cure persisting till her death, twenty-seven years later. In his experience with 100,000 cases of eye affections he has encountered only 559 of detachment of the retina. When there is still perception of light, he advises repeated sclerotomy, a pressure bandage, diaph resin with jaborandi, and purgatives. These measures will sometimes cure the detachment permanently, as in the case especially reported. Uthoff has cured 28 out of 337 patients treated by sclerotomy, as he is going to relate in detail at the Lisbon congress. Deutschmann has also had 7 patients cured for over ten years by this means.

71. Treatment of Retention of Testicle.—Katzenstein reviews the anatomic conditions and affirms that operative treatment of the testicle retained in the inguinal canal should not be attempted before the eighth or tenth year, although when complicated with hernia it demands immediate treatment at any age. He operates by drawing the testicle down into place with a thread passed through the tunica albuginea and tunica vaginalis of the retained organ. After the thread is thus passed through the testicle, through an incision over the inguinal canal, it is seized from below with long forceps introduced through the scrotum. The testicle is thus drawn down into place and is held there by being fastened to a flap from the inside of the thigh, about the size of a quarter, with a broad pedicle. The under side of this flap is sutured to the testicle, four stitches embracing the tunica albuginea. This holds the testicle and stretches the spermatic cord. Every step taken exerts traction on the cord by means of the attached flap from the thigh. After a few weeks the cord becomes permanently stretched, and the base of the flap uniting it with the thigh can then be severed. He has performed this operation fifteen times on 10 individuals. In every case the testicle has remained in its normal place and has grown in size. The wounds were treated with bismuth or a paste, and protected with a light dressing. The patient was kept in bed for a week or so and the leg gradually used. Others have modified his original procedure by fastening a string to the testicle and passing the string around the foot, thus exerting traction on the spermatic cord

from the foot. Longard and Lanz fasten the testicle to the thigh with adhesive plaster, but this is not sufficient in case of a very elastic spermatic cord. Others still have implanted the testicle in the thigh, but general anesthesia is required for its final restoration to place. Katzenstein claims that his technic is sufficient and superior, as it is simple and gives ideal results.

74. General Principles of Treatment of Wounds.—Graser dwells on the necessity for training young physicians in the importance of keeping their hands from contact with septic material. It is not necessary to take hold of soiled dressings nor feel of a pus focus. With practice one soon learns to change the dressings and apply ligatures without touching them with the fingers, except the ends of the suture threads. "Take away your fingers," is his constant, reiterated admonition to his assistants, so that "Finger weg" is said to be his motto. He has trained himself until he can now palpate and operate in well-fitting rubber gloves as well as without them. In the after-treatment of wounds he preaches that all wounds that can be completely sutured may be left exposed to the air. The crevices are plugged by the coagulating blood and the wound heals as under a natural scab. The surgeon has to overcome his prejudices before he is willing to leave a wound thus exposed, but the wider his experience the greater his confidence. Before the sutures are finally tied, the last drops of blood are squeezed out, and then a piece of thin gauze is laid over it, held at the edges with collodion, but leaving the wound untouched beneath it. This allows the entrance of air and favors the drying of the coagulated blood into protecting scabs. He thus treats all sutured wounds in the face, almost all laparotomies, appendicectomy incisions and herniotomies. The gauze is applied merely as a screen and can be advantageously omitted in many cases. He follows the same principles in amputations, as he describes in detail with illustrations. He writes from an experience of 500 abdominal operations, 130 amputations, 52 osteotomies and 70 resections of joints, the majority treated according to these principles.

76. Operations at the Patient's Home.—Ladenburger has performed 88 major operations at the patient's home, sometimes in a small garret chamber, and he shows how easily and satisfactorily an important operation can be prepared for in an ordinary house. He has the largest and lightest room that can be spared entirely emptied the day beforehand and wiped with wet cloths in the evening. If necessary, sheets are hung up around the walls. He believes that a private house is freer from bacilli than any hospital. Everything that comes in contact with the patient is sterilized by the operator himself, and he can thus rely on its being done to suit him. He has a nurse to take care of the patient at night, while the housekeeping is done by a woman sent by a local charitable association, the "Hauspflegeverein," which was organized to promote these operations at the house instead of breaking up the home by sending the patient, who is often the mother, to a hospital.

84. **Endomassage of Throat, Nose and Ears.**—The apparatus devised by Herz has been previously described in these columns. The patient blows into a tube, the air being conveyed by other tubes to the throat, ears or nose, with a click and ratchet, which automatically arrest the current of air intermittently. This produces a succession of puffs of air under pressure in the organs being treated and has a kind of massage effect.

85. **Potassium Iodid Intravenously.**—Doeve, *speck* pleads the use of intravenous injection of potassium iodid in fulminating cases of syphilis, or when circumstances forbid the use of mercury and rapid action is necessary. He describes 4 cases in which the rapid benefit was strikingly apparent, this prompt effect being the special advantage of the intravenous route. Very small doses prove effectual. He used .1 gm. potassium iodid, giving it in the form of 2 gm. of a 5 per cent. solution. The injection did not seem to affect the circulation, respiration or temperature, and caused merely slight pain at the point of injection, generally quite transient. In the severe cases of cerebral syphilis he repeated the injection every day for six days.

86. **Cooked Starch in Diarrhea and Sore Throat.**—For years Hauffe has used cooked starch as a soothing gargle in sore throat, and also as a means to check diarrhea. In the latter case it is sipped from time to time by the teaspoonful. It was found especially useful in the diarrhea of consumptives, but was beneficial in all varieties.

91. **Relations of Certain Yeast Fungi to Neoplasms.**—The extensive researches reported discourage further attempts to connect any of the yeast fungi with the development of neoplasms, malignant or otherwise.

92. **Congenital Tuberculosis.**—Friedmann relates the results of two years' experimental research with the aid of the dose enoument. It was noted that week-old embryos of rabbits almost invariably contained tubercle bacilli when such bacilli had been injected into the vas deferens of the parent rabbit a few weeks before coupling. If the coupling took place after an interval of more than four weeks, conception did not follow. When animals had been infected by way of the lungs, and the process had passed into a latent stage, no tubercle bacilli could be discovered in the embryos and they developed into healthy

animals. Infection by way of the peritonum became generalized so quickly that conception seldom followed coupling. A few tubercle bacilli could always be found in week-old embryos when, immediately after coupling, tubercle bacilli had been injected into the mother rabbit's vagina. Intraperitoneal and intravenous infection always prevented conception later when the infectious process was in progress. Subcutaneous infection of the mother animal immediately preceding coupling generally resulted in the finding of isolated tubercle bacilli in the liver of the fetus. They had evidently passed through the placenta. They always proved to be avirulent, and the embryos developed into healthy animals. Examination of sections of six pairs of testicles from cadavers of consumptives failed to reveal tubercle bacilli in any quantity. Only two bacilli were found. Similar sections of testicles from lepers showed swarms of lepra bacilli in the sections of the testicles. Friedmann adds that in 983 tuberculous patients with a parental history the father had been tuberculous in 51.2 per cent., the mother in 32.8 per cent. and both parents in 15.9 per cent., showing the preponderance of paternal tuberculous records. In all his experiments the embryos, although harboring tubercle bacilli, yet developed normally and were not to be distinguished from normal animals.

96. **Trauma in Relation to Affections of the Pancreas.**—Illgmann reports a case of carcinoma of the head of the pancreas developing in a healthy man of 50 at the point where he had been injured in an accident eight months before death. The case suggests the possibility that malignant disease may follow trauma of the apparently most inaccessible organs. The development of the symptoms suggested an intimate connection between the injury and the cancer.

100. **Calcification of Aorta in Rabbits After Injections of Adrenalin.**—Scheidemann's experiments have confirmed those of Josué and others, who found that long continued intravenous injections of adrenalin induced marked changes in the aorta. The changes were very pronounced in some of the rabbits, while in others they were insignificant. The changes resembled more the calcification of the media in the arteries of the extremities in man rather than arteriosclerosis. In order to approximate the conditions of the development of arteriosclerosis in man, the animals should be kept permanently under the influence of blood-pressure-raising substances, not the mere brief and intense experimental work yet done in this line. (See editorial on page 688.)

101. **Arteriosclerosis in Children.**—Oppenheimer reports 2 cases of arteriosclerosis in boys of 9 and 10. In the first the child succumbed to a spontaneous rupture of the aorta. High blood pressure and a possible congenital weakness of the wall of the artery were the cause of the affection in the first boy, but in the second it was undoubtedly of toxic origin. The pathologic anatomic findings in each case were those of typical arteriosclerosis.

108. **Prophylaxis of Streptococcus Infection Before Child-birth and Operations.**—Polano argues that the female genital apparatus is constantly exposed to physiologic wounds by the conditions of menstruation and childbirth, and that the natural resisting powers of the individual might be enhanced by artificially rendering her immune to pyogenic infection. He has succeeded in accomplishing this in laboratory animals. He induced active immunization against the streptococcus and found that the animals became far more resistant to pyogenic infection afterward than the controls. The independent re-

searches of Landmann with living streptococci, of Bumm with attenuated and of Polano with killed streptococci all corroborate each other and confirm the possibility of influencing the organism in such a way as to reduce its susceptibility to pyogenic germs later. Polano's work with rabbits has absolutely established the harmlessness of the method and its efficacy and reliability. He tested the technic on himself before applying it in the clinic, and then tried it on 60 patients who had to undergo some gynecologic operation during or immediately after childbirth. There was no suppurative in any instance, but as this so seldom occurs at the Würzburg clinic, the material is too limited for definite conclusions. Polano, therefore, appeals to others to try this method of prophylaxis on a larger scale. He uses fresh human pathogenic streptococci without passage through animals. A little human ascitic fluid is added to the bouillon to "humanize" the culture medium. Streptococci from erysipelas, puerperal and scarlet fever, anginas and phlegmons were mixed for the tests, and the bodies of the bacteria were alone used. By this means 1 c.c. of injection material corresponded to 100 c.c. of the ascites bouillon or agar cultures. The bacteria are killed, centrifugated, a little phenol added and a suspension is made at the time with physiologic salt solution. He makes the injections in the pectoral muscles as causing less annoyance in lying or sitting than if made in the buttocks. There is a very slight general reaction, the temperature rose a trifle and the pulse rate was increased a little in the experiments on himself with twice the amount he used on others. He calls this technic "a means of inducing natural antiseptis in the individual." The organism is affected by it in such a way that it is able to offer a successful resistance to the streptococci and annihilate them at their first invasion.

109. Perfect Laparotomy Cicatrix.—Exact apposition of the layers of the abdominal wall is indispensable for a perfect suture and cicatrix. A special mode of suturing after incision of the linea alba was introduced into Küstner's clinic some years ago, and 157 patients thus treated have been re-examined lately. The results have been so satisfactory that Haines describes his technic for the benefit of others. The peritoneum is sutured separately with catgut and tied. The single thread for the fascia and epidermis is passed through the fascia and then the ends are crossed and passed through the epidermis from below. The suture thus forms a figure 8, the upper half larger than the lower. Aluminum bronze wire is used for the figure 8 suture. From seven to nine of these sutures, not too close together, are required for a laparotomy. The wire is removed about the fourteenth day. The results are as fine with this simple technic as have been hitherto attained only by more complicated methods of incision and suturing.

110. Ovariectomy During Pregnancy.—Graefe reviews the cases reported since Heil's statistics were published, and adds 4 others personally observed. The mortality of ovariectomy during pregnancy is actually less than at other times, but this is due merely to the fact that a malignant ovarian tumor prevents conception. The pregnancy proceeded uninterruptedly to term in all but 2 cases. This can be insured by postponing the ovariectomy in case of a living child nearly to term. Out of 23 cases on record in which both ovaries were removed before the end of the fourth month, abortion followed in 4 instances, the percentage being about the same as for unilateral ovariectomy. Graefe believes that an ovarian tumor in a pregnant woman should be removed as promptly as possible. He operated by the abdominal route in his cases.

111. Influence of Gynecologic Affections on the Blood.—Leisewitz has been investigating the blood in 150 gynecologic patients. The examinations were made in the morning, after a night breakfast, the day before the operation. The findings were so constant and so characteristic that he declares that examination of the blood should never be omitted before any important operation for a severe gynecologic affection. It supplements the indications for operative or nonoperative treatment, especially in case of myoma and of innocent and malignant cystoma. When the blood is examined before the operation and again afterward, it reveals the influence of the affection and the improvement of the general condition after operation. Myoma and carcinoma have a decidedly unfavorable influence on the blood, inducing high leucocytosis, with great reduction of the hemoglobin content, but these conditions soon

right themselves after removal of the growth. He classifies the findings in the various groups of gynecologic affections. In 3 cases of tubal abortion there was a hyperleucocytosis of 40,000 in one patient eight days after the rupture of the tube. There was no suppurative, but the findings suggested that there had been three separate hemorrhages during the interval before the operation. If the blood findings show a tendency to improvement in cases of myoma in which the indications for operation are dubious, non-interference for the time being may be justified if the blood is examined again every three or four months. In case the blood findings show a tendency to grow worse, operation should not be delayed. If the blood findings were very abnormal before an operation for myoma, the prognosis should be guarded. In case of low hemoglobin and small number of reds, the possibility of degeneration of the heart should be borne in mind.

113. Relations Between Uterine Fibroma and the Heart.—Out of 36 patients with uterine fibromas in von Lingen's experience, only 16 presented evidences of functional cardiac disturbance of the heart; 5 others had a murmur at the apex, probably due to anemia. The particulars of all his cases are tabulated, and the necessity for careful examination and watch over the heart in all cases of uterine myoma is emphasized. If slightly abnormal conditions are found in the heart, this is another indication for removal of the growth, as also for heart tonics. The prognosis is better than when the heart and vessels already present pronounced changes. In operating it must be borne in mind that a vaginal operation makes less demands on the heart than a laparotomy.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

IMMEDIATE EXAMINATION OF UTERINE MUCOSA AND MYOMATOUS NODULES AFTER HYSTEROMYOMECTOMY TO EXCLUDE MALIGNANT DISEASE.*

THOMAS S. CULLEN, M.D.

Associate Professor of Gynecology, Johns Hopkins University.
BALTIMORE.

It has long been known that sarcomatous changes may occur in myomata. In 1860¹ Virchow gave a very clear account of the gross and histologic pictures in such cases. In 1872² Chrobak drew attention to this class of cases, and in 1887³ Ritter gave a full survey of the literature up to that date. The question was fully discussed by Williams,⁴ as well as by Schreier,⁵ in 1894; and in 1895 by L. Pick.⁶ The article of Gessner,⁷ published in 1899, is the most exhaustive that we possess, and will well reward a thorough study. Among the more recent and lucid articles is that of Wier,⁸ published in 1901, and that of Jacobi and Wollstein,⁹ which appeared in 1902.

But it was the excellent paper by Charles P. Noble, that first thoroughly aroused gynecologists to an appreciation of the possible danger of allowing myomata to remain year after year without operative interference. His paper was closely followed by those of Hunner and McDonald. In going over the large number of myoma cases that we have had at the Johns Hopkins Hospital I have been surprised at the number of instances in which myomata were associated with carcinoma either of the cervix or body, and at the relatively frequent pictures of sarcomata developing in myomatous tumors. All these cases will shortly be reported in detail by Dr. Kelly and myself.

These findings have a very practical bearing, and at the New Orleans session of the American Medical Association in May, 1903, I advised opening the uterus immediately on its removal as a routine procedure to see if by any chance carcinoma of the body existed.¹⁰ Since that

meeting I have seen several cases that indicate a still further precaution, namely, that we not only carefully explore the uterine cavity at once, but also examine the myomatous nodules. Had such a precaution been adopted in the present case there is a strong probability that the patient might have been saved. The uterus on removal showed nothing unusual. On opening the uterine cavity the mucosa was found everywhere intact and apparently normal. Further examination in the operating room was not undertaken and the specimen was sent to the laboratory. There a longitudinal section was made through the tumor and some degenerative changes were noted, but through an unfortunate circumstance no further examination was made. It was not until after the second operation, more than two years later, when we found a sarcoma springing from the cervical stump, that the original tumor was again examined. The most casual glance showed not only areas of hyaline degeneration in the myoma, but also round and irregular areas of typical sarcoma.

Supravaginal hysterectomy supposedly for simple interstitial and subperitoneal myomata. Two years later sudden collapse due to hemorrhage from a sarcoma developing from the cervical stump (Fig. 1). Re-examination of the original tumor showed typical sarcomatous transformation of the myoma (Fig. 2). Later intestinal obstruction; artificial anus with complete control. Death eight months after the second operation.

Patient.—Mrs. W., aged 42, was seen in consultation on Jan. 22, 1903. For several years the menstrual periods have been exceedingly free. From time to time she has been treated for dyspepsia and for some cardiac lesion, but not until recently has any abdominal enlargement been detected. She is well nourished, but is exceedingly pale. The mucous membranes are blanched and the hemoglobin is 30 per cent. On vaginal examination the cervix is found to be normal. Filling the vaginal vault and extending half way to the umbilicus is an irregular myomatous uterus. Above and to the right is a globular mass the size of a kidney. One of the most interesting phenomena is a bruit felt by the examining finger along the course of the left uterine vessels.

Operation.—The uterus was brought up without much difficulty and the large mass felt in the region of the liver proved to be a subperitoneal and pedunculated myoma. The uterus was removed from left to right. The left tube and ovary were not disturbed. The patient stood the operation well and lost very little blood. Phlebitis developed some days after operation, but did not retard her progress very much. Within a month her color had returned, and in less than three months she was in perfect health. I saw her on Jan. 1, 1905, and she was in excellent condition.

Second Operation.—Feb. 17, 1905. The patient felt perfectly well and went to market yesterday morning. About 1 p. m. she was taken with pain in the lower abdomen, and a little later on almost fainted while at stool. Dr. Gortler was called to see her and advised immediate removal to the hospital.

On examination, under anesthesia, we found the pelvis partly filled by a mass about the size of a small cocoanut. This apparently involved the left side more than the right. The left ovary having been saved at the previous operation, we thought

that this tumor was certainly ovarian in origin. On opening the abdomen the left ovary was found to be perfectly normal, but projecting from the stump of the cervix and extending down between the cervix and rectum was a definite sarcomatous nodule fully 10 cm. across (Fig. 1). This was somewhat lobulated. It had been slightly lacerated and free bleeding had occurred. We removed at least a quart and a half of free blood and clots from the abdominal cavity. Her sudden discomfort was evidently due to partial tearing of the growth. We were able to peel the growth out to a great extent, but it was impossible to remove it in its entirety.

The left lobe of the liver was sharp, the right lobe very blunt and thickened. We thought that we were dealing with a hepatic metastasis, but on continuing the incision upward found there was merely thickening of the liver. The omentum was free. The appendix was removed.

FIG. 1. Sarcoma developing in the cervical stump (Gyn-Path. No. 8270). The pelvis is viewed from above. Rising from the pelvis between the bladder and the rectum is a smooth lobulated growth presenting a somewhat scarred appearance. To the left is the intact and normal left ovary. The right appendages were removed at the first operation.

The condition is particularly interesting when we remember that the uterus had been removed fully two years before and that for two years the patient had remained perfectly well.

Postoperative History.—Patient was readmitted to the Church Home Aug. 21, 1905. For the preceding four or five weeks she had had great difficulty in securing an evacuation of the bowels. On examination we found that the pelvis was practically filled with a new growth and that it would be necessary to make an artificial anus. The bladder showed definite involvement by the growth and the urine contained large quantities of blood. I made an incision through the left rectus, brought out the sigmoid flexure, cut it in two, closed the lower end, brought the upper end out through the rectus, passed it outward beneath the sheath of the rectus for about an inch and a half, then made a longitudinal section through the sheath of the rectus and through the fascia to the skin,

attaching the bowel to the skin. The bowel, therefore, was brought upward, then outward and then upward again. The patient experienced a great deal of relief. Her bowels moved once or twice a day, but she had practically absolute control, as there was no escape of fecal matter except at stool. She improved considerably. Occasionally there was some discomfort from the rectal tenesmus due to the ever-increasing growth pressing on the remaining portion of the rectum; otherwise she was comfortable. She remained in the hospital until about the first of October. During the last two weeks of her life she became much weaker and died Oct. 30, 1905.

Description of the Sarcoma Developing from the Cervical Stump.—The specimen (Fig. 1) consists of a mass of tissue 10 by 8 by 5 cm. It is somewhat lobulated, is rather smooth and on its under surface has a basal attachment, extending over an area of about 5 by 5 cm. The tissue is of brain-like consistency, yellowish white in color. It tears with the utmost readiness. On section the mass is found to contain a large irregular area of hemorrhage. At one point is a cystic space 2 by 1.5 cm. This is divided by trabeculae into smaller spaces and is filled with blood clots. The general character of the growth is clearly evident without histologic examination.

Histologic Examination.—The tumor is found to be made up of a sea of cells. Most of these cells have oval, vesicular nuclei and bear a striking resemblance to those of muscle fibers. The cells themselves are spindle-shaped, with deeply staining nuclei two or three times the natural size. Others are irregular and also stain deeply. Again we have masses of protoplasm containing five or six deeply staining nuclei. At other points there are giant cells where the nuclei are not over one-third the usual size. In places are seen spindle cells undergoing division. There are large irregular plaques of protoplasm containing fragmented nuclei and cells showing typical nuclear figures. The nucleus itself is sometimes dividing into five or six young nuclei. The blood vessels are large and abundant. The majority of them appear to be veins. Some are filled with thrombi, and the tumor cells are gradually obliterating them. In fact, dividing tumor cells can be demonstrated lying free in such blood vessels. In some places the tissue is much rarified, and in such areas giant cells are particularly abundant. The growth is essentially a spindle-celled sarcoma which shows a marked tendency to giant cell formation.

Description of the Original Tumor.—The specimen (Fig. 2) consists of a globular uterus, approximately 18 cm. in diameter. It is smooth and glistening. On the surface one or two nodules can be detected. Attached to the right cornu is a kidney-shaped subperitoneal nodule 13 cm. in length and 8 cm. broad. It is attached by a pedicle, 2.5 by 1.5 cm., and is freely movable. The uterine cavity is 17 cm. in length and is markedly convex, owing to the fact that the growth projects inward from the posterior wall. The mucosa, on the whole, looks normal, but is atrophic. Near the fundus it has undergone in some places almost complete atrophy, the growth in the posterior wall shining through.

The greater enlargement of the uterus is due to a circular nodule, 13.5 cm. in diameter, occupying the posterior wall. This nodule is almost spherical. The central portion has, in part, undergone typical hyaline degeneration, as is evidenced by large and small spaces traversed by delicate trabeculae. On careful examination there are several areas presenting a homogeneous spongy appearance. These form a part of the myomatous tissue. They vary from 1 to 4 cm. or more in diameter, are irregular in their distribution, and have undoubtedly developed from the myomatous tissue. They give the characteristic appearance of sarcoma, and are distributed throughout the solid portion of the tumor, being also intermingled with areas

hyaline degeneration, we have a good many muscle fibers still preserved, and there are quantities of mast cells. The nuclei of the muscle fibers show considerable variation in size and in staining properties. One is instantly reminded of a sarcomatous transformation. In the more characteristic sarcomatous areas where the cells are still preserved we see the same histologic changes. The nuclei are four or five times the natural size, are irregular in outline and stain very deeply. In other places we have very large irregular cells with protoplasm which takes the eosin staining deeply, and irregular nuclei situated in the center or at the margin of the cells. Again, some cells contain six or seven nuclei. The picture instantly

suggests sarcoma, but it is impossible to tell with certainty whether the growth really started in the muscle fibers or whether it originated from the connective tissue. On the whole, we think that the evidences of muscle origin are the more reliable. In some of the hyaline areas the blood vessels still persist, but the endothelium is present and the cells of the vessel wall are stained deeply and are irregular, suggesting that the connective tissue of the vessel wall is also undergoing a malignant change. The deeply staining cells stand out in sharp contrast to the surrounding areas of hyaline degeneration. Both macroscopically and microscopically areas of calcification are evident. At no point do we find any evidence that the sarcoma extends below the confines of the myoma.

After thinking over this case the surgeon will naturally ask, "Why should we not do a complete hysterectomy in all cases?" The supravaginal operation is the easier one; it leaves a better support to the pelvic floor, there is less danger of tying the ureters, and, as the blood supply of the bladder is little interfered with there is less likelihood of a postoperative cystitis. The advantages of the supravaginal operation appear to more than outweigh the dangers from malignant changes occurring in or associated with myomata. This case, however, clearly indicates that we

should carefully examine not only the uterine mucosa for carcinoma, but also the myomata for sarcomatous changes before the cervical stump is closed.

3 West Preston Street.

Fig. 2. Sarcomatous transformation of a uterine myoma. Supravaginal amputation with return of the growth in the cervical stump. (Natural size.) (Gyn. Path. No. 6421.) The picture represents a longitudinal section through the entire uterus. *a*, Upper limit of the uterine cavity; *b*, lower or cervical portion. It is thus seen that the myoma occupying the posterior wall projected into the uterine cavity and put the mucosa on tension. The myomatous nodule is approximately circular and in many places yields the usual myomatous striation. At *c* is an area of typical hyaline degeneration recognized by its homogeneous appearance. At numerous points indicated by *d* we find sharply outlined granular or spongy areas which are at once recognized as sarcomatous. At *e* along the outer margin of the myoma are areas of sarcoma and the tissue between *f* and *f'* is partly myoma, partly sarcoma; *a* is an area of calcification.

of hyaline degeneration. Macroscopically one is able to diagnose with absolute certainty that we have a sarcoma developing in the myoma. The uterine wall posterior to the tumor varies from 1 to 1.5 cm. in thickness, and in some places there is a covering from 2 to 5 mm. of uterine muscle separating the growth from the mucosa.

Histologic Examination.—The areas indicating hyaline degeneration are entirely devoid of nuclei. Here the tissue has undergone the usual complete hyaline transformation. Many sections have been taken from the areas suggesting sarcoma. In the majority of these, most of the elements have undergone complete coagulation necrosis. Here and there, however, in the vicinity of the blood vessels, are a good many small round cells. In some of the sections, in which there is incomplete

Treatment.—As a result of German nihilism, many of the leading text-books of the practice of medicine to day are but little more than text-books on pathology. In looking through one of the latest and most popular works I was not so much surprised to read pages on diagnosis, etiology, pathology, and then to find the treatment disposed of in a short sentence. NOTE ON THE MORPHOLOGY OF BLOOD PLATES.

MARY W. ROWLEY, M.D.

BOSTON.

Blood plates are usually described as from one to three microns in diameter. The accompanying photographs* demonstrate that they are often much larger than this, with a good deal that suggests cell-structure.

The blood in which the platelets here reproduced were found was from three cases, one of pernicious anemia, one of splenic anemia and one of severe secondary anemia. Using a modification of Wright's method of staining I have obtained similar plates in cases of malaria, myelogenous leukemia and in normal blood. With this stain the definite, usually rounded outline of the periphery is distinctly shown. In most of the figures hitherto published the edges of the plates are jagged and irregular.

Why are these plates so much larger than those usually described and pictured? Their size is probably due in part to squashing, as there are more large ones near the thin edge of the blood-smeear where the leucocytes are also larger. But I believe that another reason is that with ordinary technic only the central deep-stained portion (Fig. 1) is visible at all. The periphery remains unstained and so invisible except when the platelet lies on a red cell. Then the periphery (with ordinary "Romanowsky" stain) usually appears colorless against the pink or yellow of the red cell (Fig. 2 shows a plate lying partly on a red cell with this periphery stained). I believe that with a suitable staining method plates similar to those here figured can be found in all or nearly all blood, normal and pathologic. I am now trying to work out such a staining method.

All of these specimens have been studied by Dr. Richard C. Cabot, who authorizes me to say that he entertains no doubt that the figures here shown are genuine blood-plates.

I am very much indebted to Dr. Cabot for assistance and encouragement given me by him in studying the blood-plates above described.

THE EARLY DIAGNOSIS AND RADICAL CURE OF CARCINOMA OF THE PROSTATE.

A STUDY OF FIFTY CASES AND PRESENTATION OF A RADICAL OPERATION.**

HUGH H. YOUNG, M.D.

Associate Professor of Genito-Urinary Surgery of the Johns Hopkins University.

BALTIMORE.

In the October number of the *Johns Hopkins Hospital Bulletin* I described briefly an operation for the radical cure of carcinoma of the prostate based on a study of forty cases.¹ Since then I have had ten additional cases. In the paper referred to I discussed first six cases which were seen early in the disease, in which a diagnosis of benign hypertrophy was incorrectly made and a partial operation therefore performed. (Bottini operation, 4; suprapubic prostatectomy, 1; perineal prostatectomy, 1.) All these patients subsequently returned with unmistakable evidence of cancer, and only one is alive to-

day. A study of the pathology of these cases, along with the symptomatology and clinical findings, showed that all presented certain features which may now be taken as suggestive of cancer. A study of thirty cases without operation and eight autopsies showed that cancer of the prostate may begin as a small indurated nodule in one or both lobes of an otherwise benign hypertrophy, that it remains confined for a long time within the stout capsule of the prostate, that its line of invasion is upward along the course of the vasa deferentia and seminal vesicles, and not usually into the bladder around the prostatic orifice, and that the inferior surface of the trigone is usually the first portion of the bladder to become involved.

It thus became evident that if a radical cure was to be attempted the line of excision would have to include the entire prostate, with its capsule and urethra, the adjacent portion of the bladder, particularly of the trigone, the seminal vesicles and the ampullae of the vasa deferentia.

During the course of a year four cases apparently favorable for such a procedure presented themselves, and the operation above indicated was carried out with little difficulty, slight operative shock and a very satisfactory convalescence in three cases; the histories were reported in detail. During the last six months ten patients with carcinoma of the prostate presented themselves, all beyond operative relief but one, and he would not submit to it. In one case, which seemed fairly favorable, the patient was operated on, but died, and autopsy showed extensive involvement of the pelvic peritoneum. In all of these cases the patients had been treated for a long time by their family physicians, and in several instances by skillful surgeons, and the character of the disease was not recognized. Had it been possible to get these cases earlier I believe the radical operation which I have proposed as a routine procedure for all favorable cases of cancer of the prostate would have resulted in cure.

DIAGNOSIS.

The early diagnosis of cancer of the prostate is not easy. I am free to confess that I have failed in at least six cases, and until confronted by their subsequent development never suspected the malignant nature of the disease. A study of the fifty cases which I have now had has brought out the following facts:

Symptomatology.—Cancer of the prostate may occur at any age after fifty years, 57 per cent. of the patients being between sixty and seventy years of age, the youngest in my series being fifty-three. The first symptoms in most cases were similar to those of benign prostatic hypertrophy, viz., slight difficulty and frequency of urination, but in about 30 per cent. of the cases pain was present—an unusual symptom in cases of prostatic hypertrophy. Hematuria occurred only four times as an early symptom, and in only about 20 per cent. of the cases was it subsequently present, in only a few cases as a prominent symptom; and these cases showed cystoscopically considerable intravesical tumor on growth, generally of a villous type. In a few instances the prostatic trouble ran a long course, having been present twenty years in one instance, but in these cases the disease probably became malignant many years after its onset. As a rule there has been a more rapid increase in the severity of obstructive symptoms than in benign cases, leading to an early large residual urine. In some cases, however, there has been little residuum and the bladder has been contracted.

Pain has been a prominent symptom, often entirely

out of proportion to the extent of the disease and the obstruction present. It generally appeared as a dull pain in the suprapubic region, which became worse as the bladder became full. During urination in about 25 per cent. of the cases there was pain in the urethra, often referred to the end of the penis, but sometimes limited to the deep urethra or perineum. Pain in the rectum has been present in only 10 per cent. of the cases, and seems to have no relationship to the extent of the involvement

Fig. 3.—Prostate drawn downward exposing anterior surface of the bladder which is incised by scalpel.

in the pelvis, being noticeably absent in a number of cases of extensive prostatic carcinoma. The same may be said for pain in the lower extremities, hips, thighs, buttocks and along the sciatic nerves; it has been present in cases of slight degree and absent in others of considerable involvement. When present, however, pain in the rectum and lower extremities is a very suspicious symptom and should strongly suggest malignancy. Loss of weight has been a prominent symptom.

Fig. 4.—Excision of vesical cuff carried as far as trigone. Dotted line shows site of division through trigone.

Fig. 5.—Trigone divided. Seminal vesicles and vasa deferentia exposed preparatory to division of vasa.

often occurring early in the disease and being much more pronounced than in cases of simple hypertrophy.

Clinical Findings.—The prostate was considerably enlarged in about 50 per cent. of the cases, but many of these patients were seen late. When the disease is still confined to the limits of the prostate proper this organ has generally been found only moderately enlarged. In such cases portions of the prostate in a few instances have been soft, but marked induration, generally involving almost all of the prostate, has been found in nearly all the cases. The surface of the prostate was smooth in most instances and only rarely rough or nodular until late in the disease.

Fig. 7.—Posterior view of specimen in Figure 6.

In one early case there was a small prominent rounded induration at the apex of the prostate involving also the membranous urethra. In later cases the region of the seminal vesicles has shown induration, and often a characteristic hard plateau extending across the inters vesicular space from one vesicle to the other and presenting a concave sharply defined upper border to the finger has been present. Study of pathologic specimens has shown this is to be composed of a cancerous invasion of the vasa deferentia and the tissues between them and the trigone. An unusual thickness in the retrourethral portion of the

Fig. 6.—Specimen removed; side view.

Fig. 8.—The anterior part of the vesical opening has been anastomosed to stump of membranous urethra, remainder being closed by interrupted sutures.

prostate (the posterior commissure), as shown by an instrument in the urethra and a finger in the rectum, was nearly always present. Enlarged pelvic lymphatic glands have been found in only a small number of even the more advanced cases, and as they are occasionally present with ordinary prostatitis their presence or absence is of little diagnostic or prognostic value, unless they are a prominent feature. A remarkable characteristic of cancer of the prostate is that metastases directly to the osseous system occur more often than to the glands.

The cystoscope has been of the greatest assistance in the diagnosis in early cases, as it has shown a distinct and radical difference in the intravesical picture from that seen in cases of benign hypertrophy. In the latter one usually sees two or three rounded intravesical lobes with deep sulci between and a pronounced *bas fond* behind them. In most early cases of carcinoma of the prostate practically no intravesical enlargement could be seen, and the entire absence of deep intervening clefts has been a constant finding in even the great majority of the advanced cases. Except in those rare cases in

Fig. 9.—Diagram showing plan of vesico-urethral anastomosis.

which intravesical tumors were present, if any intravesical prostatic enlargement were visible it was generally only a slight enlargement of the median portion. A picture of diagnostic importance is an elevation and puckering of the mucous membrane of the anterior portion of the trigone—due, as I have found, to the intervascular mass of disease involving the trigone and leading to its contracture. Ulceration and intravesical tumor formation has been very rare in this region and then only very late in the disease.

Before withdrawing the cystoscope I have always inserted a finger into the rectum, and the finding in malignant cases has nearly always been entirely different from that in benign cases. There has always been a much greater thickness in the retrourethral portion of the prostate, the median portion being especially thick and the consistence very hard. In later cases, in which the disease has passed above the prostate into the retrotrigonal area, it has been impossible to feel the beak of the instrument in the bladder.

Early diagnosis then may be based on a suggestive history (rapidity of growth and pain), an indurated prostate, a strictured condition of the prostatic urethra near

its apex, and the absence of intravesical lobes as shown with the cystoscope. All these conditions are rarely present together, but generally enough are discernible to make the diagnosis clear. An induration of the prostate, coming on without recent prostatitis, without catheterism or an infected bladder, in a man past fifty, with symptoms of urinary obstruction, and particularly with pain, should make the physician suspect cancer at once, and a perineal operation should be undertaken to settle the diagnosis. If residual urine in considerable amount is present without the presence of intravesical lobes, as shown by the cystoscope, the suspicion may be considered strengthened. If one is unable, however, to be certain the prostate can be exposed, as for ordinary prostatectomy, and then by inspection and palpation the diagnosis can be made certain in most cases. In some instances I have been uncertain, and have then made bilateral capsular incisions and excised small portions of the lateral lobes for microscopic study. In two cases it was shown that the irregular induration was due to seed calculi of the prostate gland and in two other cases it was necessary to have frozen sections prepared before I could be certain of the nature of the disease. With a surgical pathologic laboratory adjacent it has been possible to get a nicely stained section for microscopic study in six minutes, and I have considered this worth waiting for in several instances. I have proposed, therefore, to follow the procedures above described in all suspicious cases, and repeat that those cases in which there are areas of stony induration, with pain as a prominent symptom, and little intravesical prostatic enlargement, may be considered very suspicious.

RADICAL OPERATIONS.

As above stated, operations and autopsies have demonstrated that the entire prostate with its capsule and urethra, the seminal vesicles, the ampullae of the vasa deferentia and the superjacent portion of the vesical trigone, must be excised in one piece if radical cures are to be expected.

A study of the literature of cancer of the prostate shows that this operation has not been done before for the disease. I have excluded the case of Kuster, who removed the entire bladder and transplanted the ureter into the rectum, and the case of Harris, who excised most of the bladder with the prostate (seminal vesicles not mentioned) and transplanted the ureters into the vertex of the bladder. Both of these were suprapubic operations and the patients lived five days and five months respectively. Two cases reported by Demarquay and that of Czerny, in which the anterior wall of the rectum was excised, have also been excluded.

The operation which I have carried out in six cases as a routine procedure for cancer of the prostate is described as follows in the history of one of the cases:

Operation.—An inverted V cutaneous incision was made in the perineum as in the operation employed by me for simple hypertrophy of the prostate, each branch of the incision being about two inches long. By blunt dissection the end of the bulb and central tendon were exposed, and the latter divided, exposing, in turn, the recto-urethralis muscle, the division of which gave free access to the membranous urethra behind the triangular ligament. Urethrotomy on a grooved staff was followed by introduction of the prostatic tractor, which was opened out after it reached the bladder. While traction was made on this instrument the rectum was carefully separated from the prostatic capsule by blunt dissection until the entire posterior surface of the prostate was brought into view. Up to this point the operator proceeded exactly as in the usual prostatectomy operation. The tissues around the prostate were more hemorrhagic and the wall of the rectum more

closely adherent to the capsule of the prostate than usual. Examination of the prostate showed much greater induration than I have ever encountered in the benign prostate. The rectum and periprostatic tissues were free from invasion, and complete excision was, therefore, decided on and carried out as follows: The handle of the tractor was depressed, thus exposing the membranous urethra anterior to it at a point where it was easily divided transversely with a scalpel, leaving a small stump of the membranous urethra protruding from the surface of the triangular ligament. By further depressing the handle of the tractor the pubo-prostatic ligament was exposed and, being very tautly drawn, was easily divided by scissors, thus completely severing the prostate from all important attachments, except posteriorly (Fig. 1). The lateral attachments, which are slight, were easily separated by the finger. During these manipulations a moderate amount of hemorrhage was encountered (coming from the periprostatic veins, particularly those just behind the triangular ligament in front of the prostate), but it was easily controlled by clamping several bleeding points and applying pressure with gauze by means of an anterior deep retractor (Fig. 3).

The posterior surfaces of the seminal vesicles were then freed by blunt dissection, the now mobile prostate being well out of the wound, as shown in Fig. 2. In this exposure of the posterior surface of the vesicles I was careful not to break through the fascia of Denonvilliers which covers not only the posterior surface of the prostate, but also that of the seminal vesicles, and forms, I believe, an important barrier to the backward growth of the disease. The next step was to expose the anterior surface of the bladder, which was easily done by depressing the tractor and making strong traction. By this procedure the bladder was drawn down close to the skin wound that it was easily incised at a point in the middle line about 1 cm. behind the prostatovesical juncture (Fig. 3).

By means of scissors the division was continued on each side until the trigone was exposed (Fig. 4). After swabbing away the blood and urine, the ureters were easily found and the line of incision carried across the trigone with a scalpel so as to pass about 1 cm. in front of the ureteral orifices. While still making traction on the prostate, the base of the bladder was pushed upward with the handle of the scalpel, thus exposing the anterior surface of the seminal vesicles and the adjacent vasa deferentia (Fig. 5), all of which were carefully freed by blunt dissection with the finger as high up as possible, so as to remove with the vesicles much circumjacent fat and areolar tissues on account of the lymphatics which they contained. The vasa deferentia, after being drawn well down, were picked up on a small blunt hook and divided with scissors as high up as possible, care being taken to see that the ureters were in danger. After division of the vasa, the seminal vesicles were found to come down more readily, the deep adhesions were finally divided, and the mass shown in Figs. 6 and 7 was removed. As seen here in the side view, a portion of the membranous urethra, the entire prostate with its capsule intact, the seminal vesicles, 4 cm. of the vasa deferentia, and a cuff of the bladder 1 cm. wide along the anterior and lateral surfaces and 2 cm. wide in the region of the trigone has been removed in one piece.

There now remained a large defect to repair. The vesical opening was about 8 cm. in diameter and had sunk far back in the depths. The stump of the membranous urethra had been obliterated by the compression of the anterior retractor so that it was necessary to insert a soft rubber catheter through the urethra from the meatus to discover it. The anterior wall of the vesical opening was then caught with forceps, and I was surprised to find how easily it could be drawn down to the membranous urethra, where an anastomosis was readily made, as shown in Figs. 8 and 9. The first suture was placed by inserting the needle into the triangular ligament above the urethra and bringing it out through the anterior wall of the membranous urethra, then through the anterior wall of the bladder in the median line from within out, care being taken to include only the submucosa and muscle. When this suture was tied, the median line of the anterior wall of the bladder was drawn to meet the median line of the roof of the remaining membranous urethra; the knot was outside, and the thread was left long.

Lateral sutures similarly placed (including the periurethral muscular structures below) and two posterior sutures completed the anastomosis of the membranous urethra with a small ring into which the anterior portion of the margin of the vesical wound had been fashioned by the tying of the sutures, as shown in Figs. 8 and 9. The remainder of the vesical wound now presented a longitudinal opening which was easily closed by sutures (Fig. 8), thus completely closing the defect and replacing the prostatic urethra with a funnel-shaped process made by the bladder wall. The sutures used were silk, one end of each being left long and brought out of the wound so that they could be extracted later (since then I have found alternate sutures of catgut and silkworm gut, also left long, the best). After light gauze packing had been placed in various portions of the wound, the levator ani muscles were drawn together with catgut (two sutures) in front of the rectum and the skin wound closed on each side with interrupted catgut sutures, leaving only a small portion open at the angle in front for exit of the gauze drainage. The rubber catheter (which was of considerable service in making the anastomosis of the urethra and bladder) was fastened in place by adhesive plaster around the penis, and the patient was returned to the ward. During the operation he received 1,000 c.c. salt solution infusion beneath the breast, and his condition throughout was good, the pulse varying from 62 to 92 and being 80 at the end of the operation, which required two hours.

Examination of Tumor.—A study of the specimen removed showed adenocarcinoma involving the entire prostate, the region between the seminal vesicles and the inferior surface of the excised trigone and the vasa deferentia. The capsule of the prostate and the bladder at the upper limit of the excision were free.

Convalescence.—The patient made a good recovery. The perineal wound healed tight; there was no difficulty in urination; he was able to hold urine for three or four hours at night; there was incontinence during the day.

REMARKS ON OPERATION.

As remarked above, this radical operation has been performed on six patients with one operative death. The autopsy in this case showed extensive intraperitoneal metastases and explained the cause of death. Two patients have died since the operation, one a year later from an operation for vesical calculi. Autopsy showed a small carcinomatous mass about the size of a pea adjacent to the left vas deferens. This was the only cancerous tissue found; no metastatic glands or osseous metastases were made out. The recurrence had been predicted in this case after a study of the operative specimen which showed carcinoma near the upper end of the left seminal vesicle.

The other patient died of nephritis two months after the operation. Autopsy showed that the cancer had been thoroughly extirpated, a careful search failing to reveal any malignant disease, regionary or metastatic. Numerous sections were made of the pelvic tissues. It therefore seemed evident that had the man lived he would have remained cured of the cancer.

Three patients are living and well—one ten months, one eight months and one one month after the operation. One patient has control over his urine and can hold it several hours; one has incontinence in the day, but perfect control at night; the third is still in the hospital. All have been completely relieved of the severe pain from which they suffered before operation. None of my cases were particularly early ones. With an early diagnosis and operation the operative mortality should be nil, as only the patient with extensive (unrecognized) peritoneal metastases showed any shock.

CONCLUSION.

Cancer of the prostate is quite a common disease, about one case in seven of prostatic enlargements in men

past fifty being cancerous. It is characterized by induration—often of stony hardness, and pain is frequently present. The early diagnosis may be made when there is marked induration, and the absence of the usual intravascularly projecting lobes, as shown by the cystoscope; (the prostatic orifice often appears normal). The disease is often of slow growth and remains for a long time confined within the limits of the firm prostatic capsule. The operation carried out by me in six cases is necessary if a cure is to be expected; it is not difficult of performance, and furnishes remarkably satisfactory functional results. With early diagnosis the mortality should be nil and the percentage of cures large. The general practitioner should suspect every indurated enlarged prostate and the patient should be urged to submit to a perineal operation, when, if the disease is proved to be malignant, the radical operation can be done.

THE TREATMENT OF ANEURISM BY DIRECT, GRADUAL ARTERIAL CLOSURE.

REPORT ON THE APPLICATION OF THE METHOD TO A CASE OF ANEURISM OF THE ABDOMINAL AORTA.*

ROBERT T. STRATTON, M.D.

Surgeon to the Receiving and to the Pablos Hospitals.
OAKLAND, CAL.

RATIONALE OF TREATMENT.

The main basis for the suggestion of gradual arterial closure as a probable means of relief for certain cases of aneurism lies in three facts observed in human pathology and surgical experience:

1. Gradual closure of a large blood vessel as from the pressure of a growing tumor, so far as such pressure is concerned, is not associated with depression of vital functions nor with nutritional or other disturbances within the area of its distribution. The anastomotic current is so gradually and perfectly established that the entire absence of symptoms due to circulatory disturbances may fail even to suggest the occlusion of a large blood vessel.

2. In the larger proportion of those exceptional cases of aneurism in which a spontaneous cure occurs this results from the deposition of the laminated coagulum or so-called active clot, on the walls of the sac, and is caused by the slowing and not the complete stoppage of the blood current in the vessel (Ashurst). It may result from any accidental cause, such as the pressure of an enlarging tumor on the artery on the proximal side of the seat of disease.

3. Aside from the radical surgical procedures which undertake, where indicated, the complete exclusion of excision of the sac or its obliteration by arteriorrhaphy, the best results in the surgical treatment of this disease, have come from methods which aim at the slowing of the blood stream through the sac, and the production of an active clot—as, for instance, in the Hunterian ligation—rather than the sudden and complete cessation of the blood flow and the production of coagulation *en masse*. Methods which cause the formation of the passive clot at best are only followed because anatomic and other local conditions prevent the adoption of procedures designed to secure the deposition of the stratified coagulum.

These three basal propositions and the principles underlying them have long been recognized. While brilliant results in many cases of aneurism, especially those involving the arteries of the extremities, have followed

the radical procedures referred to and which are not based on these principles, yet unfortunately, the proportion of those not amenable to this form of surgical treatment is large. The usual age of patients afflicted with the disease, their depressed local and general vitality, associated organic disease, the anatomic site of the aneurism, are factors which all too frequently demand the adoption of some less radical, even if less hopeful, method.

It is not to be contended that the very gradual arterial closure induced by certain pathologic processes can be reproduced by surgical means, but it is evident that the more closely these can be approximated, within reasonable limits, by the surgeon, the better will be his results both in the avoidance of risks of sudden closure and the certainty of cure by the formation of an active coagulum.

In this connection it will be of interest to refer again to cases of spontaneous cure by accidental slowing of the blood stream. Recoveries from this cause may result in the entire obliteration of the sac, the circulation being carried on by means of collateral vessels, or

Fig. 1.—Reproduction from a tracing of outlines marked on the patient's thorax and abdomen. Dotted line indicates area of aneurismal pulsation detected by light palpation; solid line, limits of aneurismal pulsation outlined by moderately deep palpation.

a narrow channel may be left running through the tumor through which the circulation may be maintained. The recognition of the possibility of cure by the latter means is of great importance in relation to the successful treatment of aneurisms from the sac of which, or from their immediate neighborhood, arteries originate supplying vital organs and which have only very meager collateral circulatory channels. Thus, in an aneurism of the abdominal aorta from which arises the celiac axis, it is manifestly impossible to adopt any radical method of cure, and what degree of relief is ever obtained must be secured, it would seem, without the sacrifice of the lumen of this branch, for the reason that its subdivisions supply the stomach, spleen and liver and have only the slightest and most indirect collateral circulatory channels. It is thus evident that in such a case the method of cure must aim at the avoidance of the complete obliteration of the sac and the process of clot formation must be carried, if possible, only so far as to stop expansive pulsation, and to leave permanent channels through the sac, maintaining the patency of the larger arterial branches arising from the wall of the

* Read before the Alameda County (Cal.) Med. Assoc.

aneurism. In the nature of things, in these cases, the best that can be attempted is the obliteration of only such portions of the sacculature as lie without the line of the main channel and of the blood currents to these branches; in some parts of the sac the process

active coagulum, however, will tend strongly, I believe, to remove this from the sphere of the imagination, and to show that in gradual and incomplete arterial closure lies the probable means of its attainment. To this, pathology and surgical experience lend strong reinforcement.

THE SLOWED BLOOD CURRENT.

Passing by the chemical and histologic truths concerned in the process of thrombosis as well as the several etiologic agencies not directly related to the production of the form of coagulum on which our present interest centers, I will consider chiefly the one factor most directly related to the formation of the stratified or mixed clot, viz., the slowed blood current. Although personal conjecture is associated with the statement of well-observed conditions, we shall later have an opportunity of seeing how far it is supported by recognized pathologic truths.

In the absence of other determining conditions, the formation of this coagulum begins first where the force of the blood stream is most reduced, at the margins of the eddies and pools in those portions of the sacculature least directly in the line of the main blood current. Here the blood platelets, the leucocytes, the fibrin and perhaps, the aggregation of a few red corpuscles produce a white thrombus. For reasons which do not plainly appear, but most likely lie in various temporary conditions affecting the force and direction of the blood stream in the sac, this clot does not at once assume the form of a considerable mass, but is deposited layer on layer, more or less irregular in size and form and thickness. Blood oozing in between these layers stagnates locally and coagulates *en masse*, producing together with the layers of white thrombus the stratified, or mixed, clot.

The nature of this form of coagulum, as well as its method of production, is quite well understood, but the extent to which its formation may be carried and the conditions influencing its form and size are not so easily discovered. Obviously, however, it would seem that the extent to which this process goes on is governed by the degree to which the blood stream is slowed. Thus, if the current is gradually and continuously reduced, the clot formation will advance with the slowing stream, gradually extending from the periphery into the central portion of the sac until, if the current is all but stopped, the entire sac is filled in this stratified way. If, however, the force of the stream is not so much slowed, the clot formation will advance only so far into the more actively moving portions of the current as the force of the stream will permit the deposition of the histologic elements and the carrying on of the chemical processes incident to clot production. In other words, when the advancing clot meets a too forcible blood current the process is stayed. If the current be still further reduced, the process will advance.

If this correctly represents the relation of the extent and form of active clot formation to the main current through the aneurism, it would seem that it explains as well its relation to secondary currents to the larger arterial branches arising from the sac. The law of hydrostatics, that pressure on a confined fluid mass is equally distributed in all directions, would be an important factor in maintaining their patency, tending as it would to make the force of the flow equal toward the lesser and greater channels, and thereby exerting the same repressive influence on clot production threatening to encroach on them. The subsequent usual contraction of the clot would tend to maintain still further their

Fig. 2.—Constrictor, actual size. All parts are made of silver except the extremity placed in contact with the artery, which is made of hard rubber. Its free borders are rounded so as to reduce traumatism to a minimum. The transverse bars near this end are made as rollers to facilitate movements of the tape. The windlass permits the regulation of the degree of pressure on the artery and the barlock fixes the windlass at any desired point.

Fig. 3.—Constrictor with tape applied to section of human abdominal aorta, actual size. The lumen of the vessel is nearly closed. Note rolling out of margin of tape. The tape is removed by cutting one side as deeply as possible in the wound with angular scissors, then turning the wheel, at the same time fixing the instrument.

may only result in the strengthening of its walls. It may seem fanciful to think this a possibility or to ascribe to any artificial method such selective properties as the accomplishment of this demands. A short review of the process of the formation and deposition of the

lumen. Thus it would seem, *a priori*, that it is possible to carry on clot formation through control of the current to the extent of completely obliterating the sac or filling a large portion of it and leaving sufficient channels to maintain the circulation not only through the principal vessel, but through its larger branches as well.

Let us see if we can secure any support to this position from pathologic observation. The so-called antemortem heart clot resulting, when for any reason the heart's action is considerably retarded, does not ordinarily form in such parts of the organ as are most directly exposed to the main blood current—the center of the cavities or the valvular openings—but, if in the auricles, they form usually in the auricular appendices; if in the ventricles, in the intertrabecular spaces where the current is least forcible. If thrombosis occurs in a vein it usually begins first in the pockets of the valves where the current is slowest. So much for the general location for the beginning of clot formation.

Can the further study of this condition throw any light on the influences governing the extent to which it may be carried? The presence of the large so-called postmortem heart clot partly decolorized, partly red, occupying the heart cavities, perhaps extending through the auriculo-ventricular openings into the vessels, has been observed by each one of us. No one doubts that its presence in those localities, ordinarily the site of a fast-moving stream, is due to the very feebly flowing blood current incident to death or the complete stagnation immediately following. Why, then, in cases of pronounced antemortem white thrombus, formed while there is still considerable force to the blood stream, is it not found in those localities and why its periphery ordinarily limited to a point not far beyond the line of the most direct and forcible blood flow? Is it not due to the repressive influence of the more actively moving current beyond the limits of which it can not advance? Will not the same thing explain the fact that after ligation of an artery the coagulum extends to the first collateral branch, while in a vein with its lower blood pressure a clot once beginning to form may extend indefinitely, even to the heart?

Does not the occasional cure of an aneurism by accidental events wherein is found a channel, perhaps only a narrow one, running through the aneurismal mass and through which the circulation is continued, tend strongly to prove the same thing? To be sure, clot formation in the sac may partially break down after its complete filling, and tunneling may result with its permanent channel formation; but, on the other hand, it does not seem to be forcing matters to regard the channel as frequently the result of the continuance of a force to the blood stream of sufficient degree to prohibit the advance of the clot to the extent of entirely obliterating the cavity of the sac. Finally, my personal experience with the case of aneurism presently to be described, wherein the function of organs whose blood supply came through arterial branches having their origin in the sac was not apparently interfered with, although clot formation had advanced so far that appreciable expansive pulsation and thrill had ceased, tends strongly to confirm the position taken that the process of coagulation can be thus controlled.

THE TREATMENT DEMONSTRATED.

If the principles on which rest the suggestion of the cure in certain cases of this disease by gradual closure of the artery are sound, it only remains to demonstrate

a practical method. Two questions, especially, in this relation demand an answer:

1. Can such a procedure be followed and infection avoided?

2. Can the prolonged direct pressure necessary to induce gradual closure be made on the arterial wall without serious damage to its tunics or to adjacent structures?

In reply to the first question it may be stated that the open wound maintained patent for a number of days, perhaps involving the peritoneal cavity and requiring occasional exposure, is a matter to be seriously considered. Yet I believe that no one to-day will affirm that in a patient capable of co-operating with the surgeon, modern aseptic and antiseptic technique scrupulously followed, not only at the original operation, but throughout each subsequent treatment, is unable sufficiently to guarantee a reasonable degree of safety concerning the avoidance of infection.

As to the second question, the experience of Crile in temporary direct closure of the carotid arteries in operations on the head and neck, the experiments of Keen in temporary complete closure of the abdominal aorta in dogs, and my own series of experiments on dogs to ascertain the feasibility of gradual closure of the abdominal aorta and the effects of prolonged moderate pressure on it¹ go a long way toward proving that at least in healthy arteries, it is possible to maintain a reasonable degree of direct pressure for a considerable period of time without seriously endangering their integrity. As a further proof I desire to present the following case wherein direct pressure was applied continuously to the upper portion of the human abdominal aorta for fifty-one hours without apparent damage to the vessel. The case is unique in that it is probably the first instance wherein any such procedure has been attempted; and probably also in this case direct surgical attack was made on the abdominal aorta at a higher point in its course than has heretofore been made. That the artery was atheromatous is an additional point of interest, as my previous similar operations had been practiced on dogs with presumably healthy vessels.

I would much prefer to postpone this report until a more extensive personal experience had accrued, and my reason for not doing so at this time is that further opportunity for investigation along this particular line, as will be readily understood from the knowledge of the comparative infrequency of aneurismal disease in this locality, may be long deferred, and it seems to me that the results already attained and the lessons thus far taught are of sufficient importance to warrant their announcement.

My attention was first called to this question of gradual occlusion in 1898, in connection with the difficulties attending the necessity of formally resecting, in what seems to have been the first recorded instance, the superior longitudinal sinus. In a paper² containing a report of the above case I referred to the desirability, under certain conditions, of closing the sinus by a gradual method in order to insure the establishment of the collateral circulation, and suggested the use of specially constructed clamps. In a subsequent communication³ I stated that the "method of gradual occlusion of a sinus suggested in the original paper, with a modified technique,

1. "The Gradual Surgical Occlusion of Large Arteries: Its Relative Advantages, Together with an Experimental Inquiry as to Its Feasibility." *Annals of Surgery*, August, 1902.

2. "The Surgical Occlusion of the Cerebral Sinuses." *Annals of Surgery*, August, 1898.

3. *Id.* January, 1899.

has a probably wider range of application to the surgery of the blood vessels than was then intimated. * * *

"The importance of this in the surgical treatment of aneurisms of the large arteries, as well as in other conditions will be readily appreciated." In the fall of 1898 I had undertaken to test the practicability of gradual occlusion by the application of a clamp to the abdominal aorta of a dog, and in a paper¹ I described further experiments on dogs tending to strongly prove its feasibility.

That I am able at this time to present additional proof is due to the courtesy and professional enthusiasm of Dr. T. A. Williams, who requested me to see the patient in this case and to follow my own judgment as to operative procedure. To him also I am indebted for the privilege of making the clinical report.

History.—Male, aged 53, Greek, vegetable dealer. There is no history of syphilis nor of the excessive use of alcohol. He had scars resulting from glandular suppuration in both inguinal regions. Four years previously he had complained of distress in the epigastrium which developed gradually. In August, 1903, he underwent a laparotomy for abdominal aneurism at the French Hospital, San Francisco. What attempt at relief was made was not known to the patient. His greatest complaint later was of pain in the lower dorsal region and in the epigastrium. Four months before my visit he had become addicted to the use of opium, but subsequently was cured of this by Dr. Williams. The pain so increased, however, that the use of morphin was resumed and one grain a day had been administered hypodermically and gave considerable relief. His weight had decreased from 190 pounds, when his trouble began, to 147.

Physical Examination.—I first saw the patient in March, 1905. His general condition was fairly good. Physical examination showed unmistakable evidence of the existence of an aneurism of the abdominal aorta of large size. The peripheral arteries were not appreciably atheromatous. The usual signs of expansile pulsation and bruit were present, and even the epigastrium was seen to pulsate forcibly. A consideration of the chart (Fig. 1), reproduced from a tracing of outlines marked on the patient's thorax and abdomen, will reveal the position and relations of the aneurism and will explain some of the difficulties of the operation described. The dotted line shows the area of the epigastrium within which most superficial palpation detected the aneurismal pulsation, while the solid line represents the limits of aneurismal pulsation outlined by moderately deep palpation. It will thus be seen how close the aneurism approached to the ensiform cartilage. As nearly as could be estimated the distance was only 5 mm. The ensiform cartilage was 4 cm. wide at its base and 4.5 cm. long. The distance between the margins of the costal arch at the level of the tip of the ensiform cartilage was 10 cm.; between the tips of the eleventh ribs it was 22 cm. The size of the aneurism, as estimated by deep palpation, was 9 cm. in both vertical and transverse diameters. The lower border was 3 cm. above the umbilicus. A cicatrix resulting from the former operation was noticeable, and its character indicated healing, accompanied by suppuration.

Operation.—Operation was performed April 5, 1905, with the assistance of Drs. T. A. Williams, A. S. Kelly and J. M. Shannon. A median abdominal incision was made extending from the base of the ensiform cartilage well down over the aneurism. It was soon evident that conditions resulting from the first operation would complicate matters and make operation much more difficult than otherwise. The parietal peritoneum, liver, stomach and omentum were everywhere adherent to each other where normally in contact. The liver, where visible in the wound, was scarcely recognizable, being of a peculiar yellowish-brown hue. It was separated from the abdominal wall, partly by tearing away its capsule and leaving it adherent to the peritoneum and partly by incising adhesions and peritoneum. The entire ensiform cartilage was removed to gain space for necessary manipulations above the aneurism. In doing so the xiphoid artery was incised and ligated. The lower border of the left lobe of the liver was incised longitudinally for about 3

cm. between catgut sutures to gain space for the hand and instruments. After separating the lesser curvature of the stomach from the liver, to which it was closely attached, the lesser omentum was perforated with the index finger and the aorta sought beneath the posterior parietal peritoneum above the aneurism. The latter was pulsating forcibly from beneath the stomach and pancreas against the hand, against which it was firmly pressed because of the limited space between the aneurism and the liver and diaphragm. This constant impact made detection of the aorta extremely difficult. Pulsation in what seemed to be the abdominal aorta from its location could not be positively determined. What seemed to be the right border of the vessel was most distinctly felt and the peritoneum over it was torn through. This was accomplished with a long-handled scarifier with which I had provided myself to be used in case the peritoneum resisted the finger nail. The index finger was then passed beneath the aorta. The peritoneum along the left margin of the vessel was torn through with the scarifier, and the finger was passed completely beneath the aorta, when it was positively recognized, not by forcible pulsation as I expected to find—in fact, the absence of this was especially noticeable, although its recognition was doubtless prevented by the constant rhythmic impact of the aneurismal sac against the examining finger—but by a peculiar whirling sensation or thrill imparted to the sense of touch by the blood current deflected from its direct course. The absence of pronounced expansile pulsation at the point of constriction is worthy of special notice as having a direct bearing on the question of the feasibility of prolonged instrumental pressure on the artery without damage to the arterial tunics, and no doubt accounts largely for the fact that appreciable injury was not wrought by this procedure. It may be accounted for by the firmness of the adventitia of the aorta.

Complete momentary stoppage of the flow of blood through the aorta caused entire cessation of pulsation in the aneurism. Considerable venous hemorrhage attended the separation of the adherent organs and the dissection of the aorta, and on this account and because of the depth of the vessel and the fact that the possibility of retraction of the superficial structures was very limited because of the rigidity resulting from the preceding inflammatory process, most of the steps of the procedure had to be carried on by the sense of touch alone. The part of the aorta reached by the finger, so far as could be determined, seemed pliable and healthy, although situated close to the aneurism. At this stage, 11:20 a. m., a cotton tape, 12 mm. wide, reinforced longitudinally along its central line by a tape 4 mm. wide and the whole impregnated with paraffin² and attached at one end to the arterial constrictor³ (Figs. 2 and 3) was passed from left to right beneath the aorta on the point of a hook-shaped instrument which was guided by the index finger beneath the vessel. This proved to be the most difficult part of the operation. The free end of the tape was then attached to the constrictor, which was tightened so as to make apparently a very slight impression on the aneurismal throbbing. More was not attempted for the reason that the general condition of the patient at this time was not encouraging, and it was thought best to avoid doing anything that might still further depress him. Gauze packing loosely applied was arranged spirally around the constrictor and extended from the aorta out through the skin opening to prevent contact of the metallic parts of the instrument with the viscera which would have caused local necrosis, to control venous hemorrhage and to cause adhesions to be formed around the constrictor thus to shut off the general peritoneal cavity from the site of operation in case, notwithstanding our efforts at its prevention, sepsis should occur. The constrictor thus ap-

4. This arrangement of the tape was made as tending to cause the borders of the wider tape to flare outward, thus reducing to a minimum the amount of traumatism due to the impact of the pulsating arterial wall against the tape margin. The instrument also was designed to effect the same end. Paraffin was used to prevent adherence of the tape to the vessel. The portion of the tape only which is to be in contact with the artery, the whole being sterile and dry, should be merely dipped in boiling paraffin and the excess thoroughly removed from the tape.

5. For several valuable suggestions in regard to the constrictor I am indebted to Mr. Ole Olson, surgical instrument manufacturer, of Oakland, Cal.

phed rose and fell with each aortic pulsation. The abdominal incision was closed around the gauze and instrument. The latter was covered with loosely fluffed gauze and cotton and the dressings so arranged that no pressure would fall on the constrictor. The patient stood the operation comparatively well. He was soon conscious after its close. He vomited slightly at this time.

Postoperative History.—April 5, 4:20 p. m.: The patient was in good condition; pulse, 84. There was considerable seepage of blood, and the wound was redressed. The constrictor was tightened until a decided impression was made on the aneurismal pulsation and on the femoral pulse. After this the pulse was 80. The patient was not distressed by this procedure. At 10 p. m. he was in good condition; pulse was 84.

lately on account of the motion transmitted to the neighboring parts by the constrictor and the aortic pulsation. The patient said that he did not feel different than before this last increase in the degree of constriction. After this the pulse was 84 and the man rested quietly. At 5 p. m. he was in good condition. He vomited twice without much retching. The pulsation in the femoral artery was more pronounced, but still very feeble. Deep palpation over the aneurism revealed a feeble thrill. The tapes were tightened until the thrill disappeared; this very slightly reduced the force of the femoral pulse. The patient did not complain much of pain. There was some slight hic cough. After tightening the tape the pulse remained at 84. The extremities were warm; there was no paralysis of motion or of sensation in the lower limbs.

April 7, 8 a. m. The general condition was excellent; the patient passed a good night. The femoral pulse was larger, and pulsation over the site of the aneurism was noticeable, but a thrill was not discernible. Inasmuch as I was of the opinion that the constrictor was applied below the celiac axis, and being emboldened by Keen's report of a case wherein he applied a ligature to the abdominal aorta, "whether above or below the celiac axis was not quite certain, but it was surely applied above the renal and mesenteric arteries," without prolonged circulatory disturbance, the constrictor was further advanced and the femoral pulse abolished. Pulsation over the site of the aneurism was less pronounced, but still discernible. It was not expansile, however, nor was a thrill discoverable. After constriction was complete the patient became restless and complained of pain in his back and tingling in his lower extremities. The pulse before final constriction was 76; a few minutes later it was 78.

Unfortunately the patient's condition grew rapidly worse following this treatment, and I was summoned to the hospital at 2:15 p. m., when he was moribund. His pulse was rapid and feeble and just perceptible at the wrist; his countenance was pale and respirations shallow. The tape and constrictor were immediately removed, no hemorrhage resulting; the gauze pack was left *in situ*. This, together with active stimulation, failed to give relief, however, and the patient died at 3 p. m., less than an hour later.

Remarks.—Inquiry elicited the fact that, shortly after the closing of the constrictor, the patient became very restless and complained of pain in the lower limbs, and that after only ten minutes had elapsed there was present motor and sensory paralysis in the same

parts. The knees, legs and feet became cold, but the thighs retained considerable heat.

After the operation the patient passed urine four times: April 6, 1 a. m., 12 oz.; 2 p. m., 12 oz.; 5:50 p. m., 15 oz.; April 7, 8:50 a. m., 14 oz. A sample of urine, a mixture of the second and fourth urinations, gave the following result on examination: Sp. gr. 1020, strongly acid, no albumin or sugar, heavy sediment of urates, urea, 1.5. Microscopic examination showed urates, no pus, blood or casts. Pain and restlessness were controlled by hypodermies of morphin sulphate, gr. $\frac{1}{2}$, and atropin sulphate, gr. 1.75, to which dose the man was accustomed. One of these hypodermies were given on April 5, three on the sixth and one on the seventh, besides another of $\frac{1}{4}$ gr. morphin sulphate on the seventh. This quantity of the

FIG. 4. Aneurism and coagula removed from sac. One-fourth actual size. A. Phrenic artery. B. Site of application of constrictor. C. Celiac artery. D. Left renal artery. E. Inferior mesenteric artery. F. Right renal artery. G. Superior mesenteric artery.

full. Pulsation in the aneurism was about as forcible as before the afternoon treatment. The windlass was tightened until there was a decided lessening of force of the femoral pulse and pulsations in the aneurism were just appreciable. The constrictor had a strong tendency to bend downward and to twist from left to right.

April 6, 10 p. m.: The patient had a comfortable night, sleeping well. Temperature was normal; pulse, 84. He had no desire for food or drink. There was no paralysis; pulsation in the femoral artery was more pronounced than immediately following last constriction, but not so marked as after the previous treatment. The radial pulse was full. Constriction of the aorta was advanced so as to leave a just perceptible femoral pulse. This caused the aneurismal pulsation apparently to disappear; but it was difficult to determine this abso-

anodyne averaged, however, only about what he was receiving prior to the operation. The maximum temperature on April 5 was 99.3 F. (by mouth); on April 6, 1904; on April 7, at 5:20 a. m., 98.9; at 11 a. m., 99.2; at 1 p. m., 102.2. This last temperature was evidently due to immediate antemortem influences.

Autopsy.—Examination of the abdomen only was permitted. The operative incision was found to be approximately 12 cm. This incision and the entire operative wound and parts adjacent thereto had apparently remained uninfected. There was no hemorrhage, nor was any necrosis of viscera discovered. The intestines and peritoneum were not injected. The kidneys were congested and had the gross appearance of incipient interstitial nephritis. The spleen was congested; the gross appearance of the liver was normal. The aneurism (Fig. 4) extended from just above the celiac axis to 6 cm. above the bifurcation of the abdominal aorta. Its total length was 12 cm.; its width, 12 cm.; (these measurements were taken after the sac was removed from the body and artificially distended.) It was divided into three compartments, one in the median line extending forward 8 cm. from the spine; one compartment on each side of the spine lay alongside of the vertebral bodies. The one on the left extended vertically 7 cm. and that on the right 8 cm., each being about 4 cm. wide. The bodies of the twelfth dorsal and first lumbar vertebrae were eroded, the latter being destroyed to a depth of about 2 cm. and the former somewhat less. The aneurismal sac was attached to the spinal column. The celiac axis, superior mesenteric and right and left renal arteries around these eroded areas arose from the sac. The entire abdominal aorta with aneurism was removed.

A close examination of both internal and external surfaces of the aorta failed to reveal the site of the application of the constrictor. In my dog experiments a zone of ecchymosis discovered externally in the adventitia and minor areas of erosion of the intima internally plainly marked the site of the tape and constrictor. No such evidence of violence existed in this case. Only after the specimen had been immersed some time in a weak formalin solution did a relatively pale transverse zone, discernible on the external surface only and approximately the width of the tape, mark the place where it had surrounded the artery. It was thus seen that the constrictor had been placed about 15 mm. above the upper margin of the aneurism and 25 mm. above the celiac axis. The only evidence of traumatism discernible in the neighborhood was such as was presumably due to the removal of the specimen postmortem.¹ A number of small superficial atheromatous areas were discernible in this part of the aorta. Several very small ones were beneath the site of the constrictor.

The aneurismal sac was moderately well filled with large masses of laminated coagula aggregating 350 c.cm. in volume. They were all of recent origin and of different consistency, being most firm where lying in the more direct line of the blood current. Besides these masses there was a small amount of fluid blood and a trifling amount—not more than 1 c.c.—of passive clot.

Pathologic Report.—To Dr. Pauline S. Nusbanmer I am indebted for the following report on the pathologic specimens, which were submitted to her for critical examination:

"In the specimen of aneurism of the abdominal aorta I find no evidence of traumatism, neither macroscopically nor microscopically, at or immediately adjacent to the point of compression of the artery, other than that produced by manipulation during and subsequent to autopsy, and that consists of slight lacerations only. The sclerotic condition of the artery at the site of the application of the constrictor is readily detected by the naked eye, and on sectioning there is seen the thickened intima with the deeply-stained elongated cells of the atheromatous plates, but no round-cell infiltration as one would

expect to find in inflammation following injury, nor any necrotic areas such as would be produced by pressure. Eight sections of the aorta in all were made, as nearly as could be ascertained from different areas directly under the tape and constrictor, five from beneath the former and three from beneath the latter.

"The clot, of which two different areas were sectioned, is decidedly stratified and is not of the passive variety. It must be borne in mind that the time was short for many cellular changes to take place in either the vessel walls or the coagulum."

The cause of death, from a consideration of both the case history and autopsy findings, may be reasonably attributed to the inhibition of the functions of the abdominal viscera from the withdrawal of their blood supply.

Notwithstanding the fact that this patient died, the case as a whole warrants a degree of enthusiasm as to the outlook for the procedure. The relatively small amount of distress caused the patient by the presence of the constrictor and its subsequent manipulations; the apparent avoidance of infection; the safe removal of the instrument; the formation of a large mass of laminated coagulum; the apparent maintenance until entire closure of the vessel, of the lumen of the arterial branches arising within the sac distributed to vital organs and without a dependable collateral circulation; but above all the freedom of the aorta itself at the site of closure of perceptible evidence of traumatism, inflammation or necrosis due to prolonged pressure on the vessel—all these facts, I believe, form the basis of a strong hope that a larger percentage than heretofore of patients with aneurismal disease may be brought within the range of relief. If future experience shall fulfill that hope, the method will undoubtedly find its largest scope of usefulness in the treatment of aneurisms of the abdominal aorta wherein ligation is almost necessarily fatal, and other methods are either impracticable or have proved themselves inefficient or fraught with grave dangers.

Certain additional lessons are taught by this experience. The constrictor, under ordinary conditions and with a healthy or but slightly diseased aorta, can be left in place much longer than in this instance. I would not now under such circumstances hesitate to apply it for four days. This will permit the very gradual closure of the artery with the formation of a more firm coagulum. This is of special importance in relation to the treatment of aneurisms which arise high up in this vessel and from which arterial branches arise from the sac to be distributed to the abdominal viscera. It will more perfectly assure maintenance of their lumen. It will also safeguard against failure from the breaking down of the clot and against embolism when the full blood stream is again allowed to flow through the artery; the gradual relaxation of the constrictor after its work has been performed will be an additional preventive of this and will be permissible in view of the proven tolerance of the vessel to a more prolonged contact with the instrument. In the case of its application to the carotid artery, where such an accident would be disastrous, the procedure, in order to avoid this presumptive risk, may best be used as a prelude to ligation after expansile pulsation in the sac has ceased and the cerebral functions indicate the formation of a competent collateral circulation. When we consider that over twenty-five per cent. of cases wherein a single common carotid artery is ligated develop cerebral disturbance and that above one-half of those patients die (Erichsen), and that this result is probably due to failure of the prompt establishment of the anastomotic circulation, this risk does not seem so formidable. The evidence that this necropsy

7. If, by any possibility, a small transverse laceration internally, found to be located at or just below the site of the lower border of the tape, occurred other than during postmortem manipulation, it could only have been due to a defect in the instrument, which was easily corrected, and it need not, therefore, be taken seriously. A lack of sufficient space beneath the crossbars, in the presence of an excess of paraffin on the tape, caused a binding of the latter beneath the bars and an unnecessary amount of pressure on the artery during the removal of the tape.

afforded that practically no clot formation followed complete closure of the artery emphasizes the advantages of gradual over-sudden occlusion.

SCOPE OF THE TREATMENT.

It is with much hesitation that I refer to a possible larger scope for this method in the treatment of aneurism of arteries other than the abdominal aorta, in view of a single operation in man wherein this procedure was put to actual test. Inasmuch, however, as this experience seems to warrant a hopeful attitude as to the usefulness of the method, I may be permitted to take this occasion to point out other possible fields for its successful employment.

Among cases of aneurism wherein surgical attack can be entertained, it seems chiefly applicable: (1) When for any reason, local or systemic, radical operation is inadmissible; (2) In cases wherein it is feared the collateral circulation will not be promptly established in case of complete, sudden closure of the artery. It is to be recalled in this connection that the proportion of patients afflicted with aneurismal disease is large wherein the heart is fatty or its force impaired from other causes, the blood vessels are atheromatous and wanting in the usual elasticity and for numerous reasons the general vitality is reduced. Experience abundantly proves that in just this class of patients the prompt opening of sufficient anastomotic channels to carry on the circulation after ordinary ligation most frequently fails to result, and gangrene, cerebral or other disturbance according to the artery operated on is to be apprehended. In this class, gradual closure, complete or partial, if any operation is permissible, would seem to offer advantages. (3) In those cases wherein heretofore ligation has offered the best prospects, but in which it is desired to avoid the risks of failure and special dangers to life associated with that method. In ligation on the cardiac side of the aneurism close to the sac, (the Anel ligation) we must face all the dangers incident to passive clot formation, e. g.: sloughing of the sac, infection and suppuration of the sac and contents, secondary hemorrhage, gangrene, subsequent softening and breaking down of the clot and consequent failure to cure. Ligation on the distal side (Brasior operation) in addition to these has its own special danger of rupture of the sac due to the sudden local increased blood pressure. In ligation on the cardiac side at some distance from the sac (Hunterian ligation) secondary hemorrhage, gangrene and suppuration around the sac are to be feared or failure may result from a too free anastomotic circulation forming between branches of the artery arising above the point of ligation and those between the ligature and the sac.

Inasmuch as gradual arterial closure can be carried on with much less traumatism to the arterial tunics than ligation, it will be more generally admissible to apply the constrictor closer to the sac when the presence of atheroma is to be expected, than is the case with the ligature. If this is done, then gradual closure by its control of the blood current, can secure the advantage of the Anel ligation over the Hunterian of the avoidance of the formation of a too free anastomotic circulation around the ligature, at the same time avoiding the dangers resulting from passive coagulation incident to the former method. It will have the special advantage over the Hunterian ligation because of its laminated clot formation in the sac without its risk of failure of too free collateral circulation forming around the ligature. It will avoid the risk of rupture of the sac in the Brasior

operation by doing away with the sudden strain on the walls.

It would seem that gradual closure, partial or complete as indicated, secures the desirable features of all these ligation methods, while obviating their special risks. Experience must determine whether there are associated with it disadvantages peculiar to itself which outweigh its apparent claims for consideration over the ligature methods. Equally with them it will share the disadvantages resulting from large arterial branches arising from the sac. In those cases wherein these supply vital organs the decided advantage lying with gradual occlusion has already been pointed out. The application of two constrictors in certain of these cases of aneurisms with aberrant branches—one above and one below the sac—is one of the possible future developments of the method.

911 Market Street.

CASES OF FECAL IMPACTION OF THE RECTUM.*

THOMAS CHARLES MARTIN, M.D.
President Ohio State Medical Association.
CLEVELAND, OHIO.

My reason for presenting for your consideration a few cases of fecal impaction of the rectum is that they illustrate the present great advantage which we possess in the proctoscope as a means for the relief of this condition. Those more or less authoritative works on diseases of the rectum uniformly recommend that the subject of impaction of the rectum be subjected to general anesthesia and irrigation for the removal of the fecal mass. These means should be regarded as hazardous, barbarous and mussy.

The causes of fecal impaction of the rectum are several. Foreign bodies in the rectum, stricture or tumors, within or without the rectum, obstructing its lumen, immobilization of a portion of the rectal wall as a consequence of its adhesion to adjacent viscera, defective innervation, diminished intestinal secretion, the ingestion of improper foods and voluntary or involuntary neglect to make attempts at defecation.

The patient may present the history of gradually increasing difficulty of evacuation of the bowel, or he may report that for a period of a week, or two or three weeks, there may have been no dejecta. Or, on the other hand, he may report that for some time he has been the subject of diarrhea alternating with periods of constipation, the diarrhea being provoked by the presence of the fecal mass. The patient will have a furred tongue, rise of temperature, a quick and rapid pulse. I have seen patients, however, in which there was depression of both temperature and pulse. The intestine will be inflated by reason of the presence of gases, the patient will complain of cramps and a sense of heaviness and weight in the lower abdomen. Often there will be no sensation in or about the rectum excepting sacral backache, and this is usually accompanied by pain and tenderness along the course of the sciatic nerves. The diagnosis may be made by means of the proctoscope or by digital examination of the rectum.

The treatment consists of elevation of the patient's hips and the introduction of the anoscope or the proctoscope, and subsequently the withdrawal of the obturator and the illumination of the rectum by means of the best light available. I have found no more satisfactory

* Read before the American Proctologic Society, Pittsburg, May 12, 1905.

device than this candlestick (Fig. 1). The electric light here pictured might prove convenient (Fig. 2). Through the proctoscope (Fig. 3), by means of forceps and spoon, without anesthesia and without manual contact with the rectum's contents, the patient may be relieved.

CASE 1.—The first case which I report is that of a woman, 33 years of age, of Canton, Ohio, who had recurrent attacks of fecal impaction as often as once or twice a year. The only way in which the obstruction could be prevented was to secure daily a liquid stool. With much labor and by means of general anesthetics and irrigations her previous attacks had been relieved. Digital examination discovered an obstruction situated about 1½ inches above the levator ani muscle of more or less diaphragmatic form and having a circular aperture. The patient was put into the knee-chest position, the proctoscope introduced, the obturator withdrawn, the field commanded illuminated by means of the candlelight and the obstruction observed. This was seen to be a congenitally malformed valve; it presented a drumhead appearance, and in its right half a circular aperture through which could

distress and the presence of a mass, led her physicians to suspect a rectal metastasis. Examination revealed fecal impaction. The mass seemed to occupy the whole pelvic cavity. Inquiry disclosed that the woman had been subsisting on a milk diet exclusively. The feces were of an im plastic, putty-like consistency, and weighed about 2½ pounds. This patient was relieved as were Cases 1 and 2.

CASE 4.—I was called by Dr. B. to see a woman, 32 years of age, who reported that since an operation for ventral fixation of the uterus his patient had shown need for laxative medicines. This patient's rectum was impacted and obturated by the presence of scybala masses, which weighed 3¼ pounds. I believe that in this case the ventral fixation of the uterus anchored the anterior rectal wall immovably in such a degree of suspension that the woman could not effectually bear down. Without distressing her the rectum was readily emptied.

Recurrence is to be prevented largely by the removal of the mechanical cause; in Case 1 by division of the obstructing valve, Case 2 by hysterectomy; in Case 3 there was no organic or mechanical cause; and in Case 4, where the obstruction was the result of the ventral fixation of the uterus, it was inadvisable to resort to surgery. The physical obstruction having been removed, in this class of cases the patient's diet should be limited to meat, fruits and those vegetables which contain but little starch. Albumin should be given daily, the patient required to drink quantities of water and to employ the enema frequently. Proper bathing, massage and open-

Fig. 2.—The common, portable, storage-battery, pocket electric lamp.

Fig. 3.—The light being directed into the rectum, feces may be removed in the same manner as a foreign body.

air exercises should be insisted on. Cathartics are to be condemned.

I believe the report of these cases calls attention to an obviously simple method for the relief of rectal impaction of feces, and I believe that the more general practice of proctoscopy will render obsolete the employment of irrigation and chloroform or ether in the treatment of this condition.

THE BROAD TAPEWORM IN MINNESOTA, WITH THE REPORT OF A CASE OF INFECTION ACQUIRED IN THE STATE.

W. S. NICKERSON, S.D., M.D.

Assistant Professor of Histology and Embryology, University of Minnesota.

MINNEAPOLIS.

In the last edition¹ of his text-book Osler says concerning the broad tapeworm of man (*Dibothriocephalus latus*). "So far as I know it has not been found in the United States except in a few imported cases." May Braun,² in describing the distribution of this species

be observed the impacted feces. This malformed valve was now divided and the feces removed by means of the forceps and the lithotomy spoon.

CASE 2.—I was requested by Dr. B. to see a woman of 40 years of age, at her home, on the evening of Oct. 9, 1898. Digital examination discovered fecal impaction of the rectum, from which 2½ pounds of scybala feces were removed, as in Case 1, after breaking up the masses by means of long-handled scissors. The cause of the obstruction in this case was a fibroid uterus of such size as to extend from the perineal body to above the sacral promontory, thus effectually preventing the downward and backward excursion of the anterior rectal wall, which is an essential feature of voluntary attempts at defecation.

CASE 3.—In October, 1901, Dr. C. asked me to see his aunt, aged 62 years. I was told that some five or six weeks previously this patient had been operated on for the removal of sarcoma of the tongue. Her obstipation, pelvic and abdominal

2. "Die Thierische Parasiten des Menschen." 1903.

throughout the world, quotes one case as having been reported from North America (Philadelphia). Ward³ puts it also among the species "recorded from man in N. America, but probably acquired elsewhere." These citations give a fair epitome of the opinion of the best authorities in both medicine and helminthology on the occurrence of this species in America. I believe, however, that in this part of the country, which has a considerable Scandinavian, Finnish, Polish and German population, the worm is very much less rare than is indicated by the opinions quoted. Three cases in Minnesota have come to my knowledge in the past year, all occurring within one year in one town and in the practice of one physician. The worms were secured in all cases and sent to the University of Minnesota, where they are preserved, so that there remains no room for doubt in regard to the species involved.⁴

Dr. Owen W. Parker, Ely, Minn., has not only forwarded these specimens obtained by him to the university, but has very kindly furnished me with all the clinical facts obtainable concerning the cases and given me free permission to make use of such facts for publication. I wish here to make full recognition of my indebtedness to Dr. Parker's courtesy in this matter and to give him full credit for all the clinical facts recorded.

The patients in two of these cases were Finlanders, and the third case occurred in a child of Finnish parentage, who was born in Minnesota and had never been out of the state. This latter case is of exceeding interest, since there can be no question that the infection occurred in Minnesota, and it therefore demonstrates the fact that the broad tapeworm now has a foothold, at least locally, in this country. The facts of significance in the history of the case are as follows:

CASE 1.—Family History.—E. P., male, was born April 25, 1902, in Ely, Minn. His parents were born and reared in Finland. The father came to this country in 1891. Three years after coming from Finland he passed a tapeworm (*Dibothriocephalus*?) He had been ill for a year before, had lost in weight, became anemic and suffered from abdominal pains. After the expulsion of the worm he quickly recovered his health and has since been well and has shown no symptoms of infection.

History of Case.—The patient's health began to fail in February, 1904. He did not thrive or gain in weight, became anemic and gave frequent indications of abdominal pain. In August the mother noticed segments of tapeworm in the child's stools and called the physician who successfully treated him. The child has since been perfectly well.

The worm expelled Aug. 9, 1904, measured 7 feet in length and is a typical specimen of *Dibothriocephalus latus*. The scolex was secured and measures 1.75 by 3 mm. The parents say that the child had eaten many times of fish caught in the lakes about Ely and had also eaten salt fish, probably from Lake Superior, but deny his ever having eaten any imported fish.

Infection by the broad tapeworm occurs through the ingestion of the larvae (plerocercoid) embedded in the flesh of certain fresh-water fishes. No less than ten different species of European fishes are known to serve as intermediate hosts, and any of these may therefore transmit the infection. The remote possibility that the infection of the child might have come from eating some imported European fish seems to be ruled out by the statement of the parents that he had never eaten

any such fish. I am informed also by dealers that all of the fish which is imported and eaten by the Scandinavian peoples is salt-water fish. The infection could not have come through imported fish therefore, and there seems to be no possible escape from the conclusion that it was acquired from native fish, caught probably in one of the lakes near Ely or possibly in one of the Great Lakes.

It may be idle perhaps to speculate at this late date and in the absence of any detailed knowledge of the facts in regard to this patient's father. One or two suggested inferences may, however, be pointed out. As *Dibothriocephalus latus* is the most common tapeworm among the Finns it is probable that it was the species present in his case. As he had been in this country three years and had complained of being unwell only one year, and *Dibothriocephalus latus* is a very rapidly growing worm, the average rate of growth being as shown by various experimental infections of man not less than five to nine c.m. *per diem*, it would appear improbable that he could have become infected before leaving Finland and not have felt any symptoms within two years after arriving in this country. Without the case of the child's infection—which was surely acquired in Minnesota—this inference would have little significance, but in view of that case, this becomes somewhat more worthy of attention as indicating the probability that the infection of the father may have been acquired in Minnesota.

Concerning the two other Minnesota cases the following data may be given:

CASE 2.—History.—A. K., Finlander, male, aged 22, farmer in Finland and woodsman in Minnesota, was in the habit of eating much fish, often not thoroughly cooked. He had already begun to be unwell before leaving Finland, two years previously, and had gradually grown worse. His symptoms, when admitted to Shipman Hospital, Jan. 5, 1904, were headache, anemia, accelerated pulse, marked weakness so that he could not climb stairs, and palpitation. His appetite was good and he had no abdominal pains or other abdominal symptoms. He was muscular and well developed, not emaciated. The mucous membranes were pale, and the skin was of a peculiar lemon-yellow, very suggestive of pernicious anemia. There was hemic murmur and pulsation in jugulars. Blood count 1,000,000 erythrocytes, leucocytes not recorded; poikilocytosis. "In fact," writes Dr. Parker, "the blood specimen looked identical with one of pernicious anemia." After some observation and study of the case, the patient was put on anthelmintic treatment and the worm expelled. His recovery was rapid; in six weeks, when he left the hospital, he had regained his strength and color and his blood count was nearly normal, erythrocytes 4,500,000. No further record of patient has been obtainable since his discharge from the hospital. The worm (worms?) expelled Jan. 23, 1904, consisted of many (nearly 20) short pieces of a total length of 31 feet 7 inches. The scolex was not found.

This case is very interesting from the medical viewpoint, since it illustrates so well the pathologic effect resulting in some cases from *dibothriocephalus* infection and the necessity in all cases of apparent pernicious anemia of examining the feces for tapeworm eggs, since the segments of the worm are voided in rather long chains at infrequent intervals and may thus easily be overlooked.

CASE 3.—The remaining Ely case furnished a very incomplete history. Patient was a Finnish woman, aged 35, somewhat anemic and complained of colicky pains in abdomen at times and some hyperpyrexia. After expulsion of worm her health improved and abdominal pains ceased. The worm (worms?) expelled Oct. 25, 1904, was in pieces, having a total length of about 20 feet, but no scolex was obtained. In this case we have no data which in any way indicate whether the

3. "Precision in the Determination of Human Parasites." THE JOURNAL, A. M. A., 1903, p. 705, et seq.

4. Beside these specimens procured in Minnesota, there is in the Pathological Museum of the University of Minnesota a specimen of the broad tape-worm procured about three years ago from a Japanese patient in the Northern Pacific Hospital at Missoula, Mont.

infection occurred in this country or before her immigration from Finland.

A question which is at once suggested by these cases is whether the general freedom from the broad tapeworm enjoyed by native Americans is to be regarded as evidence of the absence of the species from our fauna or whether such freedom should be credited chiefly or solely to the American methods of preparing fish for food being such as to destroy any larvæ which they may harbor. For the production of infection it is necessary both that the fish eaten shall contain the larval worms and that it shall be eaten uncooked or only partially cooked. The American methods of preparing fish for food make it possible therefore to have infected fish and yet no resulting infection of man. In fact, larvæ of *Dibothriocephalus* do occur in American fishes. I have obtained them from fish caught in the Great Lakes, but without feeding experiments to rear the adult worm from the larvæ it is impossible to determine the species of *Dibothriocephalus* and the probability is in favor of such larvæ being of some species other than *latus*—the parasite of man.

It is, however, naturally impossible that there shall be larval worms in American fish without the presence also of the adult worm living in the vicinity in its definitive host. So far as we know the adult *Dibothriocephalus latus* is extremely rare in man in America generally, and there are no reports of its being found in American dogs, cats or foxes—the other animals which are known to serve as definitive hosts for the parasite. Unless the adult worm is much more common than we have reason to believe we can not expect the larvæ to occur at all abundantly or generally in American fish. The dearth of American reports regarding cases of parasitism both of man and animals leaves room for much uncertainty in regard to the accuracy of any such general conclusion as this, however, and we are by no means justified in denying the possibility that the species may be autochthonous in this country and as widely distributed as it is in Europe. On the whole, however, I regard it as much more probable that a merely local infection of the fishes has occurred resulting from the discharge into some of the lakes near Ely of feces from some imported case of *Dibothriocephalus latus* infection. That such infection should have occurred is not surprising in view of the large Finnish population of the region, the frequency of tapeworm infection among the Finns, the fact that the sewage from the town is discharged into a lake, and the large number of species of European fish which are subject to infection by the larval worms. It is unfortunate that the stringent regulations adopted by the government to prevent the introduction of objectionable species of animals and plants are by the nature of the case not capable of enforcement against intestinal parasites.

It is also to be regretted that cases of infection by intestinal parasites are not generally reported by the physicians under whose observation they come so that they become a matter of permanent record available for statistical purposes. Although the accurate determination of the species often requires an amount of technical zoological knowledge which the physician does not have at his command, this only makes it so much more important that the specimens should be preserved and sent to some center where positive determinations can be made and recorded.⁵ If medical practitioners generally could

be induced to do this it would be the means of accumulating much useful knowledge concerning animal parasitism in this country, a subject that has heretofore received far too little attention from physicians. We need to know more fully what human parasites occur in America, their frequency, their regional distribution, the sources of infection and the pathologic effects which they produce. Every case accurately determined and put on record is a contribution toward this end.

Now that it is shown that infection of American fish by the larvæ of *Dibothriocephalus* is possible and has occurred locally, it is important that all possible measures shall be taken to prevent the infection from becoming widespread. To this end the physician's influence should be exerted wherever necessary to prevent the eating of fish food not thoroughly cooked and to prevent the feeding of raw fish to domestic animals. Where a case of infection by the broad tapeworm is known to exist the thorough disinfection of all fecal discharges should be carried out to prevent the possibility of living eggs being carried into any stream or lake. In cases of *Dibothriocephalus* infection all possible data should be gotten which may tend to show where the infection was acquired.

INSANITY AS A RESULT OF HYSTEROTOMY AND OÖPHORECTOMY.*

GRAEME M. HAMMOND, M.D., LL.B.

NEW YORK.

Gynecologists have generally accepted the hypothesis that the ovaries influence the development of the brain and that their removal is generally followed by consequences disastrous to that organ. Many things have contributed to this opinion. In a great many cases insanities do follow operations for the removal of the pelvic organs. Dudley¹ voiced the opinion of gynecologists when he said: "It would seem as if the ovaries, and probably the testicles, add something to the system which is necessary for the individual's complete development, and by removing the ovaries or testicles you deprive the system of something that causes a perversion of nutrition."

Again, it is the belief that the early removal of the ovaries and testicles causes changes in character in man and in the lower animals. This is true in so far as the sexual instinct is obliterated, and as the sexual instinct profoundly influences the course of life, such as, for instance, the maternal and paternal instincts, the desires for pleasing the opposite sex and the battling with the world with the object of gaining a home, wife and children, the individual is changed to that extent, but there is nothing to show that the early removal of the generative organs in either sex diminishes mental vigor, intellectuality, or is conducive to insanity or to mental degeneration. The doctrine that the ovaries secrete some substance necessary for the preservation of the integrity of the brain will not, of course, hold good for the uterus, and it is well known that the same psychoses which follow operations on one follow operations on the other. Disease of the ovaries, which gradually destroy their function, is rarely followed by insanity, but the operation for the removal of the diseased and destroyed ovaries is often followed by mental disease.

Against the theory that the ovaries are necessary for the preservation of the mental faculties is the fact that

5. I will undertake willingly to receive specimens of human intestinal parasites from physicians in Minnesota and adjacent states for determination. All specimens should be carefully preserved, and as full data as possible should be sent with them.

* Read before the New York Psychiatric Society.
1. A. Palmer Dudley. "The Trend of Gynecologic Work To-day." THE JOURNAL A. M. A., Dec. 12, 1903, Vol. XII.

many operations of a major kind are not followed by insanity at all. The fact that many women go through the menopause without mental symptoms can not be urged as an argument either way, because, though the ovaries cease to ovulate after the menopause, they might still secrete some substance beneficial to the nervous system. Insanity may follow any operation.

Piéqué and Briaud² state that all the surgeons taking part in the discussion of the Société de Chirurgie in 1898 were unanimous in the conclusion that operations on the female genital organs did not predispose to psychoses any more than other operations did. Previous to this, in 1891, the surgeons who took part in the discussion of the Congrès de Chirurgie reached the same conclusion. In this Piéqué and Briaud agree. I am not prepared to accept this view of the subject. I believe that insanity does follow more frequently from operations on the pelvic organs than from any other operation. There are reasons for this to which I will refer later.

The forms of insanity which follow operations on the pelvic organs are, first, the toxic insanities. These psychoses have no place in this article because they are caused by toxemia and, therefore, have no direct relationship to the removal of the pelvic organs.

The organic insanities are paranoia, melancholia, premenstrual delusional insanity, periodic erotic mania and paresis. Paranoia, of course, is not caused by any operation. The individual is born a paranoiac, the operation simply hastening the development of a disease ready to exhibit itself under suitable conditions. Nor can paresis be regarded properly as a postoperative psychosis. The syphilitic basis must be present in this disease. The operation with its exhaustive consequences simply develops a disease already present.

The causes for insanity, following operations on the pelvic organs, are, first of all, heredity and congenitally defective brains. I do not believe it is possible for any psychosis to develop after any operation on the pelvic organs in a healthy brain.

The psychologic causes are not by any means unimportant—the fear of death from the operation, disappointment at not being able to bear children, and the consequent curbing of the maternal instinct, the fear of the loss of the husband's love, the fear of becoming cold and indifferent to the husband, and the fear of acquired masculinity—all exert a powerfully depressing effect on the mind, and contribute, in a brain predisposed to insanity, a great influence in developing psychoses.

Such physical causes as anemia, neurasthenia and the breaking down of the general health from long-continued disease, also influence a tendency to the development of a psychosis. In almost all cases the patient has suffered for months and even for years from an exhaustive disease before operative procedures are advised, and this exhaustion and malnutrition is certainly influential as a causative factor in insanity. Surgical shock is by no means an unimportant cause.

My position on this subject is that the ovaries and uterus have nothing to do with the preservation of the integrity of the brain, and that their removal alone never causes insanity; that the insanities which follow operations on these organs depend on a hereditary tendency to insanity, the psychologic causes and the physical causes, and the surgical shock already referred to, but that the principal cause of all is the congenitally defective brain.

THE NAUHEIM BATHS AND TREATMENT OF HEART DISEASES.

G. WACHENFELD, M.D.

Sanitätsrat.

BAD-NAUHEIM, GERMANY.

During my stay in the United States an article by Dr. J. M. Anders¹ of Philadelphia on the action of the Naueheim cure attracted my attention. I deem it my duty to say a few words in reply to his statements, both in the interest of Naueheim and of Americans suffering from heart diseases who are unable to visit Naueheim for relief.

Those not acquainted with Naueheim and the prevailing conditions who read these statements must be led to the conclusion that it is a generally accepted practice at the place to treat heart disease with gymnastic exercises. This is by no means the case. The fact is that out of fifty physicians practicing in Naueheim the Schott treatment is solely applied by Professor Schott. A number of the Naueheim colleagues still occasionally permit the patients to exercise with the Zanders apparatus, but not until the muscles of the heart have been sufficiently strengthened by the bath treatment, which means near the termination of the cure. Then they apply preferably apparatus which produce passive movements, and particularly movements which tend to induce deep breathing without the least active exertion on the part of the patient, thereby not causing overworking of the heart. The number of physicians who reject even these apparatus is considerable. They rely mainly on the baths; prescribe all the rest possible and try with the aid of additional means, such as massage, diet, etc., to unburden the heart. During the last season over 26,000 people came to Naueheim to take the bath treatment. Of this number certainly by far the majority were not treated by the Schott method. In spite of the absence of this treatment, the results have been, to say the least, equally as good. Therefore, I am fully justified in the assertion that Dr. Anders has given the gymnastic treatment an importance to which it has absolutely no claim. To attribute recovery from diseases of the heart in Naueheim to the exercises is absurd; it is the Naueheim baths, plain and simple, which constitute the essential curative factor. Before entering more specifically on the bath treatment I wish to explain why I could not—without harm to the interest of patients not able to visit Naueheim—allow the misleading statements of Dr. Anders to remain unchanged.

Frequently during my stay in the United States I have had the opportunity to discuss with my American colleagues the treatment of heart diseases in general. Invariably I have been informed that heart patients were subjected to gymnastic exercises, and in many instances I was referred to articles on this subject published by Schott, Thorne and other authors, and more than once my attention was drawn to Dr. Anders' paper. I was repeatedly assured that following gymnastics the area of dullness was diminished and the pulse rate reduced. But does that actually prove anything for the efficiency of gymnastics? I hardly think it does. On the contrary, I consider gymnastic exercises in most cases of heart diseases, especially myocarditis, under all circumstances very dangerous. Gymnastics are not without danger in any case, because in all cases of heart diseases the myocarditis is more or less affected, too. It is the more dangerous where the neutralizing

2. Piéqué and Briaud: "Études de psychoses postopératoires," *Arch. de Neurol.*, Second Series, No. 15, 1903.

agent of the Nauheim baths can not be given at the same time to counteract the damaging effect of the exercises. In other words, I consider the treatment of heart disease with exercises, especially in those cases where the Nauheim baths are not available, extremely dangerous. Where a diminution of the area of dullness has been found, following gymnastic exercises, there is by no means a certainty that the actual size of the heart has decreased. At best the percussion of the heart is of a conditional value. To be of value it is necessary that the consecutive examinations by percussion are to be made under exactly the same conditions. The position of the heart is changed with the variations of the amount of the stomach's contents, and in like manner an expanded lung replete with air changes the boundaries of the area of dullness. In support of the latter contention in particular I refer to the work of my Nauheim colleagues, Grote and Reissner.² Both colleagues have by an extensive series of very carefully conducted investigations determined that the bath produces an increased depth of the respiration, and the consequent expansion of the lungs causes the deceptive appearance of the reduction of the size of the heart. The same increased expansion of the lungs, which also follows the deep respiration which Schott advises during the exercises, must be held responsible for the reduced pulse rate—not the gymnastic exercises.

Schott contends that by gymnastic exercises, by vigorous stimulation of the heart's action, in one of his first publications on this subject—if I am not mistaken—he uses the term *Herz-Turnen*—the muscles of the heart are strengthened. He assumes in this connection that the same conditions prevail with the diseased muscles of the heart as with weak and poorly developed external muscles of the body under voluntary control. There can be no doubt that muscles, otherwise healthy, that are below the average in their development may through systematic exercises be brought up to the normal, and more emphatically I contend that this capacity can be increased above the standard. I need only refer to the excellent results of physical culture and scientific training under the direction of competent men practiced at your American colleges and universities. With patients visiting Nauheim we do not deal, except in the rarest instances, with healthy or merely poorly developed heart muscles, but with pathologic changes, and often with degenerative processes, sometimes of the gravest nature. Weak and diseased muscles of the heart can never be strengthened by increasing their burden, but by lightening it, which means rest. It has been my experience that absolute rest of the heart, through diet, massage, sun baths, etc., are followed by the more certain results. I trust the reliability of my observations will not be questioned, as the greater part of my patients are constantly under my supervision, i. e., those who stay at my sanatorium.

Now, in regard to the influence of the Nauheim baths, I can readily understand that anyone who lacks the opportunity of observing a greater number of heart cases in the place itself will consider the matter somewhat skeptically. It appears at first thought incredible that twenty or thirty baths, or even a few more, should bring about such potent influence on a diseased organ, and yet this is actually the case. The fact that the number of patients afflicted with heart troubles in the last decades has annually increased considerably in Nauheim tends to show that more and more physicians and patients

alike are becoming convinced of the efficiency of the Nauheim baths.

What produces the effect of the bath? In my opinion, we need not look for a difficult explanation. In all chronic diseases we find metabolic disturbances. We all know that the lymphatic circulation bears a very important relation to metabolism. Now, the plain water baths bring about a stimulating influence in moving the body fluids, and in a more marked degree this action is found where the baths contain an increased amount of salts. Add to this the proper conditions of temperature, the presence of carbonic acid gas, as in the Nauheim waters, and other agents of physico-chemical nature, which have not yet been definitely determined, and the action of baths is increased to a vigorous stimulation of the lymphatic circulation. In addition, Nauheim enjoys the exceptional advantage of a great variety of bathing forms, which enables us to grade the baths to suit the indications of the weakest as well as the more resistant patient. It naturally follows that a thorough treatment at Nauheim is to be preferred to one at home. But not all patients suffering from heart troubles can visit Nauheim, and for various reasons a great number must be content with home treatment. If at Nauheim it is proper to aid the baths by dietetic treatment and measures directed toward unburdening the heart—these include the Abée heart-support—certainly all these must apply in a larger scale to a treatment at home where the artificial substitute must naturally fall behind the efficiency of the original Nauheim baths. At any rate, over-exertion of the diseased heart, gymnastic exercises in whatever form, can not be too strongly condemned.

THE MEDICAL PROFESSION AND THE MEDICAL JOURNALS IN RELATION TO NOSTRUMS.*

FRANK BILLINGS, M.D.
CHICAGO.

Primarily, the medical profession is to blame for the present extensive use of proprietary medicines, of which the majority are nostrums.

The law of demand and supply applies here; if we did not prescribe them, they would not be manufactured.

"There's millions in it." The medical profession is blind; we do not see that we are the dupes of men as fertile as Colonel Sellers in schemes and far more practical than he, in that they put their plans through to a finish.

Commercial cupidity exists in all the walks of life. It is small cause for wonder that shrewd men should take advantage of an opportunity that is lucrative and at the same time so easily exploited.

As it seems to me, the chief causes are evident. A large number of the medical profession do not practice medicine rationally. They have no clear conception of disease processes. They do not study and examine their patients. No diagnosis is made at all, or only from subjective conditions. Symptoms are treated. Headache, backache, indigestion, albuminuria, cough, constipation, dysmenorrhea, insomnia, nausea, dyspnea, etc., call for drugs, with usually no attempt to get at the underlying cause. I regret to say it, but I believe that many, many

* Read at the meeting of the Suffolk County District Society of the Massachusetts Medical Society, Jan. 3, 1906. A report of this meeting, with the discussion, appeared in *THE JOURNAL*, Jan. 20, 1906, p. 220.

2. A report appearing in the *Münchener med. Wochsft.*, October, 1903.

physicians practice medicine on that basis. Think, for a moment, of the vast number of proprietary mixtures, usually nostrums, advertised and distributed in samples to physicians as symptomatic cures.

This sort of practice requires a vast number of these nostrums. He who treats symptoms must necessarily change the medicine from time to time to satisfy and to hold his patients. He relies on ready-made, symptom-indicated, dose-directed, usually palatable medicine. He believes what he reads in the "literature" of nostrums sent to him or as it appears in the advertisement found in his medical journal. He forgets that this testimony is inserted for pay. He sees testimonials from professors and practitioners praising the remedy and he believes.

But he is tickle and drops his last specific cure-all for a new one, which comes to him in sample, by mail, or is presented to him by the traveling agent in a confidential and instructive (?) way, and again he believes. He forgets that this agent is either a doctor, who has failed as a practitioner, or an ex-drug clerk whose full worth is commanded by ten or fifteen dollars a week. Usually the physician is told that the preparation is ethical, and that its formula is published (usually, however, without indicating the amount of the constituents of the mixture contained in a dose). The process of manufacture is dwelt on—"after painstaking research" the mixture is so put up that new and heretofore unheard-of potency is developed in it.

It is a common experience of druggists to have a rush of prescriptions for a nostrum which has just been sampled to the physicians in the neighborhood.

For ways that are dark the exploiters of copyright preparations are sufficient and proficient. The nomenclature of these compounds is a wonder. No especial system is followed. A catchy name appears to be the main thing. The name may consist of a euphonious combination of the alleged ingredients; of a morbid symptom or process combined with a drug; of a name indicating the alleged number of ingredients in the mixture, or of any coined word that is striking in print or sound. So we have Sanmetto, Ferrolenn, Salochinin, Peptomangan, Uric-Antagon, Antiphlogistine, Zymoticeine, Gonosan, Anasarcin and Antikamnia, Duofonol, Quarfonol and Sextonol, and Urotrene, Chionia, Cystogen, etc., as examples. 'Apeitzo is a breakfast food, and the name makes one hungry. It is said to be an iron food. Apetol is a medicine, a strengthener which strengthens, composed of a dozen or more drugs. Rheumagon suggests a possibility that the "rheum" had "gone," but it is said to contain sodium iodid and sodium phosphate, and to cure rheumatism and all conditions resulting from uric acid in excess and disturbed metabolism. This is not the only uric acid annihilator, for they are numberless. The average proprietor of a trademark preparation looks on uric acid as one, if not the worst, enemy of mankind. He offers us uric-acid solvents in the form of natural mineral waters (recently these are radioactive as well), artificial waters, salines, plain and effervescent—all things to "touch the liver," and so every one concerned is happy, except a majority of the patients.

Often a chemical or drug is used by different proprietary firms in a mixture of other and often indifferent substances and presented in powders, tablets, etc., under different copyright names. For instance, Hexamethylene-tetramine, which is recognized as an excellent antiseptic in diseases of the urinary apparatus, is ex-

ploited in mixture in a dozen or more trade names by as many firms. Cystogen, uriform and aminiform are examples. Acetanilid is exhibited in mixture as bromoseltzer, antikamnia, orangeine, phenalgin, ammonol, megrimin, etc., by different proprietary houses. Some of these mixtures have even been presented as synthetic chemicals. Well-informed physicians believed this until the Council on Pharmacy and Chemistry of the American Medical Association made known the formulæ after analyses of the mixtures.

It may be well to say, in passing, that mixtures which contain poisons, like opium and its derivatives, chloral, cocaine, strychnin, arsenic, acetanilid, should be properly labeled, with the amount of the drug contained in the mixture. It is a common occurrence in Chicago to find patients suffering from chronic acetanilid poisoning due to the continued use of the mixtures which contain acetanilid, but which do not indicate the presence of the drug in the preparation. They are advertised as cures for fevers, colds, cough, as tonics, as "bracers," etc.

I am very sorry that acetanilid was made official in the last Pharmacopeia as *Pulvis Acetanilidii Compositus*. I think it too dangerous a drug to be used as a medicine, and especially when there are so many harmless substitutes.

But to return to the nomenclature. It is contrary to all scientific standing and progress. It is meaningless. Without a scientific terminology, pharmaceutical preparations cannot be studied or learned. The deception practiced by the nomenclature of the nostrums is detrimental to all scientific progress and to the morals of the profession and is harmful to humanity. But the nomenclature is linked with a most astounding statement of physiologic action and therapeutic indication in the "literature" of these preparations and in the advertisements in medical journals. Let me quote a few of these statements:

"Hexamine." "It is invaluable in cystitis of all kinds, albuminuria, gout, gravel, incontinence of urine, pyelitis, pyelonephritis, renal and vesical calculus, phosphaturia, rheumatism and irritable bladder from any cause. In typhoid fever it prevents the spread of the infection and destroys the colon bacillus."

"Who could ask for anything more definite and universally applicable?"

"Sanmetto is not an excitant or stimulant. Its purpose is soothing, healing, restoring. It soothes the irritation, heals the diseased mucous membrane and restores tone to the enfeebled parts. By its use the genitourinary organs are built up to a state normal with the age of the patient, and thus at the same time any pathological conditions that may be present as a result of their impairment are relieved or cured."

This negative and positive statement of a tonic which soothes and heals and does not excite or stimulate but cures is better than the fabled fountain of youth.

"Antiphlogistine." "It depletes the visceral blood vessels by flushing the superficial capillaries—bleeds but saves the blood."

I wonder if any sensible-thinking doctor believes this. If he does, I'd like to know why.

"Caseo-Metris." "A laxative utero-ovarian tonic, alterative and sedative." "It contains the purely active matter from aleris, cramp bark, wild yam, squaw vine, black haw, blue cohosh, golden seal and cascara sagrada, the inert and objectionable elements being eliminated. Free from alcohol and sugar. Very palatable. A decided advance in modern therapeutics."

Could you ask for any better example of a "shotgun" dose, and that, too, a laxative, a tonic, a sedative and alterative!

"Tongaline." "Antirheumatic, antineuralgic. Cures rheumatism, sciatica, lumbago, grippe, neuralgia, malaria, headache, gout, because Tongaline contains standard remedial agents of absolute purity, combined with salicylic acid made from the natural oil of wintergreen. Tongaline acts upon the poisonous products of retained excretion or perverted secretion and eliminates them promptly and thoroughly, thus insuring in every instance certain results from certain doses in certain time."

Verily, this is too much! At this rate there will be no reason to die. The practice of medicine with tongaline is too easy.

"Pil Orientalis (Thompson). "The therapeutic value of ambrosia orientalis (imported solely for ourselves) as a powerful nerve and brain tonic and powerful stimulant of the reproductive organs in both sexes can not be overestimated. It is not an irritant to the organ of generation, but a recuperator and supporter."

This ought to answer, once for all time, the statement of certain quack advertisers of "Lost manhood, how restored!"

"Sulpho-Lythia." "Is a true hepatic stimulant, intestinal, antiseptic, antizymotic and toxine eliminator."

This is almost as good as the statement of the old woman of Irish extraction who praised the effect on the bowels of sulphur and molasses: "Sure, the molasses 'iles 'em and the sulphur moves 'em."

"Anasarcin." "Absolute cure of dropsy caused from heart, liver or kidney troubles."

These are strong words, but they are justifiable. From every quarter come enthusiastic reports of clinical results accomplished by prescribing anasarcin, not only in dropsies, but in exophthalmic goiter. All those natural speculations in the doctor's mind as to the usefulness of this remedy should be immediately dismissed."

The statement of an absolute cure for dropsy, of any cause, is enough to condemn a preparation.

"Glycozone is daily making converts among physicians for its wonderful work in inflammatory and contagious diseases of the alimentary canal. It is the rational treatment in gastric and intestinal disorders, such as dyspepsia, gastritis, gastric ulcer and all contagious and inflammatory diseases of the stomach and intestines."

Such converts as this stuff makes among physicians are not worth saving.

"Physicians everywhere prescribe Triacol (Alpers) with unequalled success and perfect satisfaction in bronchitis, coughs, pharyngitis, laryngitis, phthisis tuberculosis. They prescribe it because it cures."

It is prescribed because it cures tuberculosis, bronchitis, laryngitis, etc. The physician who would prescribe it on the basis of the statement made should have his license taken from him.

"Alettris Cordial Rio is indicated as a prophylactic remedy against postpartum hemorrhage, uterine weakness, great development of the fetus and of the adnexa, and in those cases where there is a disposition to hemorrhage."

A prophylactic against uterine weakness (what is it?), great development of the fetus! Good Lord! What next?

These are some of the statements made in the advertisements of a few of the many proprietary medicines. The majority of the quotations are from medical journals. One is not surprised to receive the scarlet literature of the nostrums through the mail. Nor is one especially shocked to find reports of impossible cures and astounding statements in the medical trade journals, for such journals are published wholly in the interest of proprietary houses; but one is disturbed to find that the regular and otherwise respectable medical journals pub-

lish such rubbish as I have quoted. Such advertisements will be found in the *Medical Record*, *New York Medical Journal*, *the Medical News*, *The Boston Medical and Surgical Journal*, *American Medicine*, *British Medical Journal* and *London Lancet*. Recently the pages of THE JOURNAL of the American Medical Association have been purged of some of the objectionable advertisements, but still advertise some medicines with very objectionable statements as to the therapeutic effect.

Now I, and I think most people, believe that the advertising pages of a medical journal are a legitimate part of the publication. Editorial responsibility should extend to every part of it. There can be no question of the harmful effects on the profession of the flood of nostrums. It is injurious, therefore, to promote in any way the use of them. The editor of a medical journal can not escape the responsibility of the character of the reading matter, and the influence it may have, which appears in his journal.

The term "ethical" appears in many of the statements of the proprietors of nostrums. The word covers a multitude of sins. The Standard Dictionary defines ethics as "the science of human duty; the science of right character and conduct." The alleged curative properties of preparations quoted above and of many others advertised in medical journals and in the other "literature" circulated in various ways do not conform in any way with the definition of the word.

Indeed, the method of advertising these "ethical" preparations in the medical press would, with very little alteration, fit any "patent" medicine advertised in the lay press.

To illustrate I quote from the lay press:

"What is Castoria? Castoria is a harmless substitute for castor oil, paregoric and soothing syrup. It is pleasant. It contains neither opium, morphin nor other narcotic substance. Its age is its guarantee. It destroys worms and allays feverishness. It cures diarrhea and wind colic. It relieves teething troubles, cures constipation and flatulency. It assimilates the food, regulates the stomach and bowels, gives healthy and natural sleep. The children's panacea—the mother's friend."

This is, like the "ethical" advertisement in positive-ness of statement, both affirmative and negative.

"Tonsiline is the greatest throat remedy on earth. Tonsiline cures sore throat of all kinds very quickly and is a positive, never failing and speedy cure for sore mouth, hoarseness and quinsy."

As this appears in a newspaper, the profession will say it is a quackish statement made to fool the laity. But as bad and worse statements concerning nostrums appear in medical journals.

"Ask your own doctor; if he tells you to take Ayer's Cherry Pectoral, for your severe cough or bronchial trouble, then take it. If he has anything better, then take that; only get well as soon as possible, that's the object. Doctors have prescribed this medicine for sixty years. We have no secrets. We publish the formulas of all of our medicines."

Now, can you see any great difference in the alleged curative powers and the therapeutic indications of the preparations quoted from the lay journals and the medical press? In fact, there is none. The language used in the advertisements placed in the medical journal is a little more technical and, for that reason, is often not so rational as the statements made in the lay press.

The medical press is an educator. Through it, more than by any other means, medical knowledge is widely disseminated. It is a power which, when properly directed, yields untold riches for the benefit of the medical profession. But it has an equal power for evil. If

it, as an educator, contains material which is false and misleading, even though this is confined to its advertising pages, it does an infinite harm to the profession and to mankind.

I have not met an editor who defends the practice of advertising nostrums. Confessedly it is done for money, not for the editor, but for the publisher. The excuse offered is that the editor is engaged to edit the medical articles; the publishers print the journal and supervise the advertising department; but this is not explained to the reader. To the average man all printed statement is fact. He believes the printed word when he would doubt the oral statement. This is the result of our methods of education of children. They are taught to believe all they read. Many persons never discover the fact that, as Burns says:

Some books are lies frae end to end,
And some great lies were never pen'd;
Ev'n ministers, they have been ken'd,
In holy rapture,
A rousing whid, at times to vend,
And naill't wi' Scripture.

The proprietary medicine evil is due chiefly to the credulity of the medical profession. The cupidity of the proprietors and promoters is the second cause, and, unfortunately, the medical journal lends itself to the exploitation of the nostrum.

Few of us probably realize the extent to which the use of proprietary medicine has grown in a short period of time. To judge by the prescriptions filled in drug stores of large cities, at least 50 per cent. of the members of the profession use proprietary medicines.

The statement is made¹ that in New York City about 70 per cent. of the prescriptions filled in large drug stores call for proprietary preparations. This statement is a general one and probably not definite.

In Chicago I have secured data from two drug stores. In one large downtown drug store 42 per cent. of the prescriptions contained proprietary medicines. This pharmacy fills the prescriptions of physicians who in many instances occupy high places in the profession.

The second drug store is in a residence neighborhood where chiefly the prescriptions of the family physicians are filled. This showed about 50 per cent. of prescriptions calling for out-and-out proprietary mixtures or containing, in part, a proprietary chemical or drug. One prescription was for Ca-toria and California Fig Syrup, equal parts, with directions to take a teaspoonful every two hours.

In Boston there was secured the data from two of the best known druggists. In one, in which 14,895 prescriptions were filled in a year, 38 per cent. were proprietary; in the second, in which 12,000 prescriptions were filled in a year, 48 per cent. called for proprietary medicines.

Modern medicine has established the fact that specific medication for disease is very limited. The specific sera, used as antitoxins and bactericides, organotherapy in a very limited field, quinin in malaria, and mercury and iodids in syphilis, comprise the list. A rational use of drugs, preferably in simple form to stimulate or to maintain the physiologic function of organs embarrassed by unhygienic habits, by an acute infective process or partially crippled by a morbid anatomic process, is the chief reliance of the physician.

Palliation of suffering is an important therapeutic measure. The rational, careful and conscientious physi-

cian primarily attempts to make a definite diagnosis. The removal of the cause, when possible, is an important step with a rational management of the personal hygiene. The drug treatment may be a very important part of the management, and it requires a fine judgment to know when and what to give in disease, as well as when not to give anything.

The Pharmacopeia furnishes a list and description of chemicals and drugs, more than enough to meet the wants of the most ardent believer in drug therapy. A good pharmacist can furnish the official water, pill, powder, spirit, solution, elixir, tincture, fluid extract, syrup, etc., of the drugs prescribed. The Pharmacopeia gives the physician the complete and definite official mixtures. He will be able to furnish his patient with drugs at their true value. The pharmacist will not be obliged to pay a hundredfold price for the proprietary preparation, which, in the end, is assessed on the patient. Acetanilid may be bought for not more than from 25 to 30 cents a pound. If prescribed in the copy-right preparations it costs many times the trade price.

Scientific progress, professional integrity and character and economy demand the restriction of the proprietary medicine evil. To restrict it, the medical schools should teach the student, more fully and adequately, botany, pharmacology and therapeutics. The medical graduate must know how to observe and interpret the phenomena of disease, and he must know equally well the materials and how to use them with which he may combat disease. He should know pharmacology and prescription writing; he should know the therapeutic value and power of drugs and their limitations. With a proper fundamental knowledge of this kind, the daily experience will add valuable information in drug therapy which will not be disturbed by the alluring advertisement of the nostrum exploiter.

To overcome the present evil will require publicity. By this means we may be able to arouse the dormant good sense of our erring brother practitioner and induce him to use simple tried and official drugs. We must induce the physicians to attend medical meetings and to rub against their fellows. But at these meetings we must not permit the exhibition, under our auspices, of pyramids of proprietary medicines and stacks of more "literature" than is offered at the scientific sessions. We must discountenance the practice of the "faculty" and the practitioner in writing testimonials of the wonderful effects of these cure-alls.

We must induce our medical journals to stop advertising nostrums. The editors of the great journals of the country are to be numbered among the best members of the profession. If they choose to do so, they can permit the advertisement only of those proprietary medicines which furnish for publication, in the advertisement, an authentic, definite and complete formula. They should also edit the reading matter of allowable advertisements and prevent the abuse of overstatement and the publication of untruths. Secret mixtures and mixtures with incomplete formulas or with indefinite statements as to the constituents should be refused space in the reputable medical press. With the publication of accurate formulas the physician would be able to judge of the possible virtues of the mixtures. To most of us, mixtures with known formulas are objectionable. Disease is never quite the same in different individuals, and the morbid phenomena are not often expressed in the same form from hour to hour and day to day. The treatment must be modified to meet the varying prob-

1. James J. Walsh, M.D., *THE JOURNAL A. M. A.*, vol. XIV, No. 23, p. 1762.

lem of the morbid process. This can be done much more helpfully with simple drugs than with intricate mixtures.

Secrecy is essential to the success of the nostrum evil. Publicity will kill it. Publicity will educate the physician and the public and teach them not to use secret mixtures which often contain poisonous chemicals or drugs which are kept secret for the purpose of assigning to them alleged virtues and that an extravagant price may be obtained.

Finally, I desire to express sorrow that the present status of the nostrum evil compels me to say a word of complaint of the medical profession. Many physicians to whom I have talked have expressed themselves as more or less guilty of prescribing proprietary preparations. All agree that it has been done thoughtlessly and that the practice has insidiously grown on them. Many have said that it is unnecessary, is detrimental to scientific medicine, and that the exposé of the Council on Pharmacy and Chemistry will have a most decided effect in educating the profession not to use nostrums.

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XI.

INTERNAL ANTISEPTICS.

The great strides made in the use of antiseptics, after Lister had employed them in surgery with such brilliant results, led to the hope that they might be made available for limiting the development of bacteria in various parts of the human body. From time to time clinicians have reported favorable results from the use of internal antiseptics in such diseases as typhoid fever, but at the present time it is generally acknowledged that complete disinfection of the intestinal tract is impossible and that the treatment of constitutional diseases by means of antiseptics is possible only in a few isolated cases; for example, in malarial fever by quinin, in articular rheumatism by salicylic acid and its compounds, and in syphilis by means of mercurials. Quinin has been shown to have a peculiarly selective and destructive action on the protozoön which causes malarial fever, and perhaps mercury and salicylic acid may possess similar selective action against the agents producing syphilis and certain forms of rheumatism. It is no longer considered probable that there will be found any agent or group of agents capable of rendering the blood and tissues sterile to all or to any considerable number of bacteria; but it is admitted that we may yet find many agents, each exerting an influence analogous to that of quinin in malarial fever; we may limit ourselves, therefore, to discussion of the probable action of antiseptics on the alimentary canal and of the three substances just enumerated.

It is impossible to form a correct idea of the probable effect of an internal antiseptic without having at least some idea of the organisms on which it must act. Nuttall and Thierfelder took guinea-pigs from their mother by Cesarean section under aseptic conditions, and fed one of them on sterilized food for thirteen days, during which it continued to thrive, but Schotelnus found that chickens died of starvation when fed only on sterilized food. G. N. Stewart accepts Nuttall and Thierfelder's results as demonstrating that animals, including man, exist despite the bacteria which infect the alimentary canal from a few hours after birth until death.

Strassburger concludes, from a review of the extensive literature pertaining to intestinal bacteria, that Nuttall and Thierfelder have shown that no single process of alimentation is absolutely dependent on bacteria, but that the chief function of certain of them, notably the colon bacillus, which is always abundantly present, is actually to destroy other bacteria and

thus to protect the host against those disease germs which may gain entrance to the alimentary canal. The destruction of all the bacteria in the alimentary canal at any one time, therefore, might prove fatal, in that any disease germs which chanced to gain access to the intestine could so multiply as quickly to destroy the life of the host.

The proof that bacteria do play some part in the process of digestion is found in the fact that man can digest the cellulose of delicate vegetables to a limited extent, though he secretes no enzyme capable of splitting cellulose, which, therefore, must be split by bacteria present which have been shown to possess that power. Then, too, certain crystalline bodies other than leucin and tyrosin have recently been found among the ultimate products of digestion, and as none of the known digestive enzymes are capable of forming these bodies they likewise must result from bacterial action.

While we must admit that bacteria are concerned in digestion, we have no positive information at the present time as to how important a part they actually take. It has been shown that the colon bacillus, which is universally present in milk, inhibits, to a certain extent, the action of putrefactive bacteria, and it is well known that untreated milk of good quality is more digestible than is the same milk after sterilization.¹

We are thus forced, by this and other like evidence, to conclude that it is by no means desirable to render the intestines sterile and that, instead of attempting intestinal anti-sepsis in the broader sense, we should seek rather to modify the flora in that region than to destroy it.

Various methods have been proposed, from time to time, for determining the relative degree of putrefaction taking place in the intestines, but at the present time it is not positively known what constitutes the best method at our disposal for doing this. The procedure most frequently employed, one which is considered to afford a fair estimate, in a large proportion of cases, consists in estimating the ethereal sulphates in the urine. Strassburger claims that weighing the bacteria after separation from the feces and drying affords the surest means of estimating the number of bacteria present. Others count the number of colonies which can be cultivated from a milligram of feces, but this has been shown to be unreliable. In view of the fact that laboratory methods are far from satisfactory in determining the number of the several varieties of bacteria present in the feces, the general practitioner will probably be obliged, for some time to come, to depend largely, if not entirely, on the clinical data presented by each individual case.

Without knowing the precise role played by the multitudinous bacteria of many species, we do know in various ways when undue activity of the putrefactive bacteria occurs, and certain symptoms give notice that excessive fermentation is taking place in the small intestine. A moderate increase in the number of colon bacilli tends to lessen the development of the

1. Tests made on the several constituents of milk show that they have no power to inhibit putrefaction, though such a power is unquestionably possessed by fresh milk. That this is due, at least in part, to certain bacteria normally present in the milk is shown by the fact that sterilized milk putrefies much more rapidly than untreated milk on the addition of the bacillus of putrefaction (*B. putrefaciens*); but if with the *Bacillus putrefaciens* the colon bacilli be added to sterilized milk, the milk acts as does normal milk, thus proving that the colon bacillus is actually capable of inhibiting the development of certain bacteria. It is, of course, possible that fresh milk also possesses antibacterial properties which are destroyed by the sterilization. These conditions help to explain why sterilized milk is not so wholesome as new milk of good quality. It must be remembered, however, that milk is an excellent culture medium in which a great many bacteria are normally present, and that if it be allowed to stand in a warm place for some hours the micro-organisms multiply to such an extent that the milk is wholly unfit for use, and we do not wish to be misunderstood as implying that the colon bacillus is an unalloyed blessing. While, during health, this micro-organism probably does not emigrate from the uninjured intestine it may do so in states of lowered general resistance, or in the presence of defects of the intestinal epithelium, and may give rise to blood infection, or more rarely to inflammations in various organs. The possibility that the bacillus of typhoid fever and kindred forms are only modified colon bacilli is of theoretical importance. Some authorities (Escherich and some others) deny that the colon bacillus is capable of rapidly becoming virulent. Different strains of the colon bacillus have different degrees of virulence, and it still remains possible that many cases of infantile colitis are caused by certain strains (e. g., the colicollitis of Escherich).

putrefactive germs; on the other hand, an intestinal catarrh, caused by excessive acidity resulting from the undue fermentation of carbohydrates by the colon bacillus, may be alleviated by lessening the carbohydrates of the food and consequently the medium on which the colon bacillus thrives.

Normal peristalsis, by hurrying the food through the small intestine, prevents undue development of bacteria, but diarrhea and irritant purgatives favor the development of bacteria by the increased amount of liquid which is present, because of the increased secretion or diminished absorption. Thus more bacteria have been found after administration of calomel than were present before the drug had been given, though calomel is generally considered to be an excellent antiseptic.

While normal peristalsis limits the development of bacteria, the latter, in turn, liberate acids in the decomposition of carbohydrates, which probably supply the stimulus which sets up peristalsis. The normal digestion and absorption of food also tend to lessen intestinal putrefaction by lessening the amount of material which can serve as a culture medium.

It is important that the intestinal wall should be kept intact. When the intestinal mucosa is injured it fails to absorb the food products and the bacteria multiply rapidly. It has been found that many antiseptics injure the intestinal wall more than they do the bacteria, and, despite the fact that the antiseptic may be found in quantity in the feces when the bulk is small, it has actually permitted an increased growth of micro-organisms in the small intestine when other conditions favored the bacteria and not the antiseptic action. Strassburger found just double the number of bacteria after the use of naphthalene, which has been considerably lauded as an intestinal antiseptic.

As suggested before, the simplest means of diminishing the number of putrefactive bacteria is by lessening the amount of the proteid of the food. Though it has been contradicted by the indirect evidence of urinary constituents, it has been shown that the bacteria of the intestines are very much reduced in number by the withdrawal of all food.

It was formerly supposed that the gastric juice of the stomach interposed a fairly effective barrier to the entrance of living disease germs into the intestine, but this juice has but little effect at the beginning of digestion, when the activity is slight, and toward the end, when the hydrochloric acid is nearly all combined with proteid. Some micro-organisms, e. g., the tubercle bacillus, pass uninjured through the stomach more readily than others, e. g., the vibrio of cholera.

The effect of bile on bacteria is not positively known, but it is generally supposed that it does not contain any germicidal power, as some bacteria can be cultivated on bile, though not after the precipitation and removal of the mucus. The intestinal secretion does not possess any germicidal power. All these factors are important, since all of them—bile, gastric juice and intestinal secretion—have at various times been supposed to possess antiseptic properties, and it is necessary to know what results are to be expected from increasing the quantity of any or all of them.

Strictly speaking, the antiseptics of the alimentary canal should begin with that of the mouth, but this is more conveniently considered under local antiseptics. In view of the fact that the gastric juice does not interpose an absolute barrier to the ingress of pathogenic bacteria to the intestine, the proper care of the mouth and the limitation of its flora assumes an added importance, and there is no question of the fact that proper attention to the cleanliness of the oral cavity will greatly lessen the danger from intestinal infection.

The general tone of these varied statements may appear pessimistic, so far as faith in the efficiency of intestinal antiseptics is concerned, but so far from that being the case they are intended to further demonstrate that our main reliance must, after all, be placed in guarding against the entry of disease-producing organisms into the alimentary canal and their destruction before they have passed beyond the reach of local treatment. After they have once gained admittance to the intestine the best means of limiting their development must be sought in regulating the diet and careful attention to the general condition.

If we are unable to destroy all or even any appreciable num-

ber of the bacteria of the intestine, it is consoling to know that some of them are our allies instead of our foes. It is admitted by nearly all authorities that it is impossible to influence the bacillus of typhoid fever by antiseptics. It has been shown that a milk diet hinders the development of putrefactive bacteria, and many consider that the main benefit derived from a milk diet in typhoid fever is due to its effect on bacterial development. Fortunately, the *Bacillus typhosus* does not form spores and the bacillus itself is easily killed outside of the body; heating in water even to 75 C. (167 F.) for ten minutes greatly lessens its vitality.

It is practically impossible in the space at our disposal even to summarize the results of the hundreds of investigations dealing with the question of intestinal antiseptics. Those experiments which appear more nearly free from error point to the fact that we can not secure direct antiseptic action by chemical antiseptics in the intestine without injuring the intestinal wall, or at least materially reducing those conditions which naturally limit bacterial development, more than we injure the bacteria. The net result, therefore, is usually an actual increase of some species and a diminution of others. Clinical experience seems to prove conclusively that the mild mercurous chlorid, or calomel, is beneficial in those cases of indigestion which are characterized by that train of symptoms which includes a feeling of dullness, lassitude, headache, nausea and anorexia, the condition being popularly termed "biliousness." It is possible that the antiseptic action of the calomel, by limiting the development of other species of bacteria, gives the colon bacillus a chance to multiply, the increased amount of fluid in the intestine having been found particularly to favor its development. These, in turn, may then modify digestion or serve to restrict the development of putrefactive bacteria, and, as we have seen, they favorably influence peristalsis, which in turn is one of the natural means of elimination of bacteria. The increased peristalsis caused by the calomel lessens the opportunity for absorption of the bacterial toxins which give rise to the train of symptoms mentioned; this lessened absorption may be due in part to the action of calomel on the wall of the intestine. This merely suggests the many-sidedness of an operation that appears at first glance to be a very simple one. The action of the solution of hydrogen dioxide in the mouth and throat has been discussed under local antiseptics. Owing to the rapidity with which it is decomposed by mucous membranes it can exert but little germicidal action in the stomach and absolutely none in the intestine or general circulation; indeed, it is so rapidly decomposed by the blood that it speedily causes death by embolism when introduced into the circulation. The same holds true of potassium permanganate, and it is probable that all antiseptics that depend for their action on the liberation of oxygen would be decomposed in the same way when brought in contact with the mucous membranes of the mouth and throat or the organic material necessarily present in the stomach.

ACIDUM HYDROCHLORICUM.—U. S.—Hydrochloric Acid, or muriatic acid, contains 31.9 per cent. of absolute hydrochloric acid. It is seldom used in medicine in this country, the preference being usually given to

ACIDUM HYDROCHLORICUM DILUTUM.—U. S.—Diluted Hydrochloric Acid, containing 10 per cent. of absolute hydrochloric acid. This acid undoubtedly exerts some germicidal action in the stomach when present in sufficient amount, and its action may indirectly influence the intestinal flora. It has been stated that the hydrochloric acid of the stomach becomes bound to albumin during digestion and then exerts no antiseptic influence, but we have also seen that normal digestion is one of the surest means of controlling the bacteria of the intestine, and how a deficiency of that aid may cause fermentative dyspepsia, with an enormous increase of bacteria, which may become virulent. It may be mentioned in this connection that, according to some recent experiments on man, the usual dose of hydrochloric acid, 1 c.c. (15 minims) is entirely too small to supply the deficiency existing in many cases, and as much as 200 c.c. (6 fluid ounces) of 0.4 per cent. acid, corresponding to 10 c.c. of the official dilute acid, has been given with decided benefit when the usual dose or less had given no appreciable result. It must always be given diluted with a

large amount of water. It should be remembered that mineral acids are to be taken through a tube to avoid injury to the teeth, and that the mouth should then be rinsed with water, or, better still, with a mild alkaline solution,² such as lime-water or a very dilute solution of sodium bicarbonate.

NAPHTHALENUM.—U. S.—Naphthalene, naphthalin and

BETANAPHTHOL.—U. S.—Betanaphthol, or naphtol, have been highly recommended as intestinal antiseptics. As we have seen, they do not usually lessen the number of bacteria, though they may exert a favorable, modifying action. These substances have been used in the treatment of diarrhea with excessive putrefaction.

The average dose of naphthalene is given as 0.12 gm. (2 grains), and the average dose of betanaphthol as 0.25 gm. (4 grains). It has been suggested that naphthalene must be converted into betanaphthol before it can exert its antiseptic action, but even this point has not been satisfactorily determined.

There are a number of nostrums on the market consisting of betanaphthol combined with astringents, but in view of the complex nature of the problem with which we have here to deal it is preferable by far to employ the official substances, combining them as seems indicated in each case. To do this it is merely necessary to calculate the relative amount of each powder to be given at a dose and to dispense them either separately or in a single powder or a mixture.

Betanaphthol and bismuth subnitrate or subcarbonate may be combined somewhat as follows:

R. Bismuthi subnitratiss	3i	4
Betanaphthol	gr. xv	1

M. Sig.—To be made into ten powders, one being given every two hours in diarrhea with foul-smelling feces.

R. Bismuthi subnitratiss	3i ss	10
Betanaphthol	5 ss	2
Syrupi acacia	5 i ss	50
Aque camphoræ to make,	3 i i	100

One teaspoonful to be given, after shaking, every two hours.

The number as well as the variety of substances that have been suggested from time to time as intestinal antiseptics may perhaps justify a more extended review; we can do little more, however, than simply enumerate some of the official substances that have been used and are even now being lauded as valuable and efficient remedies in the treatment of the several gastrointestinal disorders.

The use of antiseptics in the treatment of typhoid and typhus fevers was first suggested in Germany more than thirty years ago, and the arguments that were offered at that time appeared so plausible that internal antiseptics at once sprang into vogue. Among the more popular were the following:

IODUM.—U. S.—Iodine is very seldom used as such at the present time, although it is official.

Average dose: 0.005 gm. (5 mg., 1/10 grain).

LIQUR IODI COMPOSITUS.—U. S.—Compound solution of iodine, better known as Lugol's solution, contains about 5 per cent. of iodine and 10 per cent. of potassium iodid in distilled water. This was at one time a favorite method of administering iodine.

Average dose: 2 c.c. (3 minims).

TINCTURA IODI.—U. S.—Tincture of iodine is virtually a new preparation and combines the strength of the former official tincture with the water-soluble properties of the unofficial compound tinctures, or soluble iodine solutions. It contains 7 per cent. of iodine and 5 per cent. of potassium iodid in alcohol.

Average dose: 0.1 c.c. (1½ minims).

Iodine and the water-soluble preparations of iodine were formerly much lauded as intestinal antiseptics, and even at the present time, though, as was shown in the introductory portion of this article, the practice is now obsolete, they are frequently exploited by manufacturers of nostrums as being little short of the ideal. The form in which iodine was formerly largely used was in connection with carbolic acid or phenol, thus:

R. Tinct. iodi	3i ss	10
Phenol	m. lxxv	5

Sig.—0.03 to 0.10 c.c. (½ to 1½ minims) three times a day in water.

Phenol itself is now seldom employed, or even recommended, as an intestinal antiseptic, but the official pheno sulphonates, better known as sulphocarbols, still have a number of ardent advocates.

SODII PHENOLSULPHONAS.—U. S.—Sodium Phenolsulphonate, the sodium sulphocarbols of the previous Pharmacopœia.

Average dose: 0.25 gm. (4 grains).

ZINCI PHENOLSULPHONAS.—U. S.—Zinc Phenolsulphonate, is rather more active than the former, combining the astringent properties of the zinc with the anti-septic properties of the phenolsulphonic acid.

Average dose: 0.12 gm. (2 grains).

Both the official salts are readily soluble in water and may be given in solution. Calcium phenolsulphonate is being lauded at the present time as an intestinal antiseptic, but there is no reason to believe that it offers any advantages over the sodium salt, and it is probably quite as harmless.

Of the other official derivatives or substances coming directly under the same classification as phenol we have:

THYMOL.—U. S.—

Average dose: 0.12 gm. (2 grains).

CHROSOTUM.—U. S.—

Average dose: 0.2 c.c. (3 minims).

GUAIACOL.—U. S.—

Average dose: 0.5 c.c. (8 minims).

GUAIACOLIS CARBONAS.—U. S.—

Average dose: 1 gm. (15 grains).

ACIDIUM SALICYLICUM.—U. S.—

Average dose: 0.50 gm. (7½ grains).

PHENYLIS SALICYLAS.—U. S.—Phenyl Salicylate, better known by its formerly official title, salol, is even now considered as being among the few really desirable or available internal antiseptics. It occurs as a white crystalline powder, having a faint but characteristic odor and a slight, rather peculiar taste; it is only slightly soluble in water and, therefore, does not become dissolved to any appreciable extent in the juices of the stomach. It is decomposed, however, by the alkaline liquids of the intestine into its constituents, phenol and salicylic acid, and thus becomes available as an antiseptic. It is said to be particularly useful in preventing the infection of the kidneys by the *Bacillus typhosus*.

Average dose: 0.50 gm. (7½ grains).

HEXAMETHYLENAMIN.—U. S.—Hexamethylen-tetramin has been discussed at greater length under diuretics (chapter v). This substance has also been recommended as an available intestinal antiseptic, but, as noted under diuretics, the ultimate products of its decomposition are largely, if not entirely, eliminated by the kidneys, and it no doubt finds its greatest field of usefulness in preventing possible infection of the urinary organs.

Average dose: 0.25 gm. (4 grains).

It is manifestly impossible to discuss or even to mention all the agents that have been, or are, employed as intestinal antiseptics. Many of the remedies that are recommended as intestinal antiseptics are also useful as anthelmintics. Notable among these is thymol, which has been referred to frequently of late as being a useful as well as an efficient anthelmintic and tenifuge.

Though many efforts have been made to treat tuberculosis by means of internal antiseptics, the favorable influence which has so far been observed is to be attributed to the beneficial effects produced on the tissues, and not to any direct bactericidal action produced by the antiseptics themselves. Of the remedies that have been suggested for this purpose, creosote and guaiacol continue to be used, probably with some benefit.

The whole problem, however, appears to concern curative effect and treatment rather than antiseptic.

Few articles in our materia medica possess any action so specific as that shown by cinchona or its chief alkaloid, quinin, in the treatment of certain forms of malarial fever. Cinchona bark itself owes its introduction into Europe to the fact that it was found to be efficient in the treatment of fevers

2. The following has been used to a considerable extent in the treatment of gastric fermentative dyspepsia, particularly when accompanied by nervous disturbances:

R. Sodii bromid	gr. v	13
Resorcino	gr. ii	1
Aque anisi q. s. ad	5 i i	10

This dose to be taken after meals in half a glass of water.

of a malarial type. For many years after its introduction into Spain the Jesuits had the bark sent to them by their brethren in Peru and carefully kept the source of its origin a secret, and the substance, therefore, became widely known as Jesuits' bark. Being virtually introduced as a nostrum, or secret remedy, it need not surprise us when we find that it has frequently taken a most important part as one of the component parts of a number of nostrums, even down to our own times.

Quinin, the most valuable of the alkaloids of cinchona, was discovered by Pelletier and Caventou in 1820, and is to-day one of the few substances in medicine that has met with a constantly increasing popularity. Quinin is official under no less than six different titles, in addition to the several scale salts and preparations that are not of direct interest in connection with its peculiar uses in malarial fever.

QUININA.—U. S.—Quinin.

QUININÆ BISULPHAS.—U. S.—Quinin bisulphate.

QUININÆ HYDROBROMIDUM.—U. S.—Quinin hydrobromid.

QUININÆ HYDROCHLORIDUM.—U. S.—Quinin hydrochlorid.

QUININÆ SALICYLAS.—U. S.—Quinin salicylate.

QUININÆ SULPHAS.—U. S.—Quinin sulphate.

Average dose of each of these preparations: 0.25 gm. (4 grains).

The physical properties of the several salts of quinin are so well known that they do not require a description at this time. The reasons for the popularity and use of some of these salts are not always apparent. In America the sulphate is used almost exclusively, while on the continent of Europe the hydrochlorid appears to be given the preference in all cases. That each of the several official preparations of quinin has some particular points of merit is suggested by the following table, showing the relative percentage of anhydrous alkaloid quinin in each and also the relative solubility in water and in alcohol:

	Per cent. of anhydrous quinin.	Solubility in water.	Solubility in alcohol.
Quinin	85.5	1750.	0.6
Quinin bisulphate	59.5	8.5	18.
Quinin hydrobromid	76.6	40.	0.7
Quinin hydrochlorid	81.5	18.	0.6
Quinin salicylate	69.3	7.7	11.
Quinin sulphate	74.3	720.	86.

It will be noted that the very commonly used sulphate, next to the alkaloid itself, is the least soluble in the most common of all solvents, water; this, while a decided advantage so far as masking the taste of the salt is concerned, is a marked disadvantage in attempting to make a solution of the salt. Where quinin sulphate is to be given in solution it must be given in an acid mixture or in solutions that are so dilute that the quantity to be taken would be nauseating.²

The more satisfactory method of administering quinin in the comparatively large quantities that are usually given is in capsules, gelatin capsules or pills.

The use of quinin as a destroyer of the protozoön which causes malarial fever is among the best established facts of therapeutics. It is mentioned here largely to avoid the criticism of incompleteness rather than to offer any suggestions of novelty to the general practitioner.

If fairly large doses of quinin be given four hours before the time at which the chill of malarial fever is expected to occur, and the dose repeated in two hours, the maximum effect of the quinin on the organism is obtained and the chill is usually prevented. The quinin existing in the blood at the time that

sporulation occurs destroys the newly liberated organisms and the blood is rendered aseptic so far as that particular organism is concerned. This process has to be repeated at intervals, sometimes for three or four weeks.

The use of salicylates in articular rheumatism is almost as well established as is that of quinin in malarial fever. The precise mode of action is not known, but it is surmised that its action is somewhat analogous to that of quinin. We may be permitted to add a list of the official preparations that would properly come under this heading, just to show the extensiveness as well as the variety of the official preparations. Surely such a variety as we find here should enable us to choose the appropriate remedy of this type without the necessity of having recourse to any of the nostrums.

ACIDUM SALICYLICUM.—U. S.—

Average dose: 0.5 gm. (7½ grains).

SODII SALICYLAS.—U. S.—

Average dose: 1 gm. (15 grains).

AMMONII SALICYLAS.—U. S.—

Average dose: 0.25 gm. (4 grains).

LITHII SALICYLAS.—U. S.—

Average dose: 1 gm. (15 grains).

STROPHI SALICYLAS.—U. S.—

Average dose: 1 gm. (15 grains).

PHENYLIS SALICYLAS.—U. S.—Salol (U. S. P., 1890).

Average dose: 0.5 gm. (7½ grains).

METHYLIS SALICYLAS.—U. S.—

Average dose: 1 c.c. (15 minims).

OLEUM BETULÆ.—U. S.—

Average dose: 1 c.c. (15 minims).

OLEUM GAULTHERIÆ.—U. S.—

Average dose: 1 c.c. (15 minims).

SALICINUM.—U. S.—

Average dose: 1 gm. (15 grains).

The use of mercurials in syphilis requires a much more extensive treatment of the subject than we can accord it in this connection, and the preparations that are usually employed are too well known to require further mention at this time.

Clinical Notes

UNRECOGNIZED EPILEPSY.

WILLIAM P. SPRATLING, M.D.

Medical Superintendent, The Craig Colony for Epileptics.

SONYEA, N. Y.

The frequency with which certain forms of epilepsy go unrecognized for years constitutes a disquieting element in the successful treatment of a disease difficult to cure under the earliest diagnosis.

1. A leading reason why certain types of minor epilepsy are not infrequently overlooked, or, being more or less casually observed, are ignored, is that we, too, often make the mistake of regarding epilepsy as "a disease characterized by tonic or clonic convulsions and followed by loss of consciousness." This faulty definition is rapidly becoming obsolete. I believe a better definition is this:

Epilepsy is a disease or disorder affecting the brain, characterized by recurrent paroxysms, which are abrupt in appearance, variable in duration, but generally short, and in which there is impairment or loss of consciousness, together with impairment or loss of motor co-ordination *with or without convulsions*.¹

The fact that this definition is comprehensive enough to include all varieties and subvarieties of epilepsy tends to rob it of scientific accuracy when applied to any particular form of the disease. But this is unavoidable, for it is more difficult to formulate a true definition of epilepsy than it is to define insanity.

1. Spratling: "Epilepsy and Its Treatment."

3. It is truly surprising that the sulphate of quinin continues to be used to the almost complete exclusion of the alkaloid and the other salts. When a tasteless mixture is desired the alkaloid is preferable because it is less soluble than any of the official salts; if it is necessary to administer the drug in solution, ten grains of the hydrochlorid may be given in a teaspoonful of a mixture containing 50 per cent. of alcohol, while three grains of the hydrochlorid, or seven of the bisulphate may be given in a teaspoonful of a watery mixture. The following is a type of the usual acid mixture:

R. Quinin sulphatis	grs. lxxv	5
Acid. hydrochloric dil.	℥ss	5
℞. Aromat. q. s.	℥ss	100

When the salt, or better, the alkaloid, is to be given in a mixture, and the taste is to be masked, acids should never be added. Instead of the acid, a sweet substance, like glycyrrhizin, should be used to mask the bitter taste of the quinin. A satisfactory mixture is obtained as follows:

R. Quinina vel quinine sulphatis	grs. lxxv	5
℞. ext. glycyrrhizin	℥ss	15
Syrup of orb. aromat. 50 q. s.	℥ss	100

2. A second leading reason why epilepsy is not earlier recognized in many cases is because the gravity of its incipient manifestations is not appreciated and because "weaknesses," "faints," "worm fits," "teething fits," "stomach fits," "lapses" and the like are often erroneously held to be innocent in character when they should always be looked on in the most serious light. During the past ten years more than 200 cases of well-defined epilepsy have come under my observation in which the disease had its origin in the innocent convulsive manifestations of early life, these manifestations being taken at their apparent rather than at their real value, and there being at the same time a general failure to respect the convulsive tendency of the individual, genuine epilepsy was sooner or later the inevitable result.

The keynote to the whole situation is in mistaking apparently innocent phenomena for phenomena of the gravest import. Muscular contractions and distortions are nothing in the prognosis of epilepsy compared to the disastrous form of the disease that may be so silent in its appearance, course and termination as wholly to escape unskilled observation. We are just beginning to learn a great truth in the treatment of epilepsy similar to the one it took us hundreds of years to learn about tuberculosis; and that is that freedom from the disease is often but little more than a matter of right living.

If a child who has "weaknesses," "faints," "worm fits," "teething fits," "stomach fits" or other lesser convulsive manifestations (no matter by what name they may be called), even though they apparently disappear for good with the passing of infancy or of childhood, the convulsive tendency of that individual must be respected so long as the individual lives, and particularly must this tendency be respected at certain critical epochs, such as the first and second dentition periods, during attacks of the specific fevers and at puberty—the latter the most of all, for from the twelfth to the sixteenth year, inclusive, constitutes the greatest epileptic age.

I make a plea for the early recognition, proper and prolonged treatment of the convulsive manifestations of infancy and early life that so often later pass into genuine epilepsy.

A NEW ANASTOMOTIC CLAMP.

G. F. ROOSEVELT, M.D.
DENVER, COLO.

The instrument presented here is designed for use in suture anastomotic work. It was originally intended for use in the operation of gastroenterostomy, but it will probably prove equally as efficient, if not more so, in enteroenterostomy.

When two clamps are used the difficulty encountered by the assistant in maintaining the proper relative position of the two portions to be united, sometimes becomes a source of annoyance to the surgeon, occasionally even leading to actual damage to the tissues. In every case it requires the entire use of both hands of the assistant, preventing his being of service in other ways.

The clamp which I have designed is expected, in the majority of cases of this class, to replace the two clamps which have hitherto been required, and the slight loss of time, if there should be any, in adjusting the new instrument in position, will be more than regained later in the operation, because the assistant will be able to save time by doing his share of the work.

As shown in Figure 1, the clamp consists of three parts—a central blade which is reversible and two blades which are interchangeable in an instrument with straight jaws, but which become right and left in a curved-jaw clamp.

The lock is a double Collins, permitting of easy separation and removal of the blades.

In a case of posterior gastrojejunostomy, for example, the stomach is grasped as usual at the desired angle, between the blades "a" and "b," Figure 2, which are then locked at the desired tension, thus virtually forming a single blade carrying the fold of stomach.

Figure 1.

The handle is now carried around to the new angle, parallel to the line "x-y" in Figure 2, or as near to it as the tissues will permit. The intestine is picked up by the fingers, or by an intestinal clamp applied in the desired line of incision, and raised up to its position against the blade "b." Blade "c" is placed into the lock which is uppermost and brought round until it clamps against "b" with the result shown in Figure 3.

Figure 2.

A strip of gauze sponge is placed along the middle blade and the operation is completed as if two clamps had been used, but much more easily.

After the anastomosis has been made blades "c" and "a" may be removed, leaving "b" in place until the field has been examined for bleeding, etc., when it may be withdrawn.

Figure 3.

In trying to hold two clamps in position there is a varying tension on the stomach which is productive of much annoyance to the anesthetist, but this style of clamp does not require that effort and supports itself on the edges of the incision with a constant tension on the stomach. It does not have to be touched from the time it is applied until the anastomosis is complete.

1423 Stout Street.

A PIECE OF STEEL RETAINED IN THE EYE FOR SEVEN YEARS.

LOUIS W. FLANDERS, M.D.

DOVER, N. H.

Patient.—Mr. J. G., aged 42, was sent to me Dec. 21, 1905, for treatment of his left eye. He gave the following history:

History.—Seven years ago, while striking with a stone chisel, a bit of steel flew from the tool and struck him with great force in the left eye. He went to an infirmary where they found the hole, but could not find the bit of steel. After six weeks of inflammation the eye quieted down, and in six months after the injury the sight was reduced to perception of light only. From that time he had occasional attacks of irritation with blurring of the sound eye, but nothing to amount to anything until the night before he appeared for treatment. He spent that night, as he graphically expressed it, "on his hands and knees in bed, shrieking with pain."

Examination.—I found a marked irido-cyclitis and advised immediate enucleation. The patient demurred, and I gave him until the following morning to decide, and in the meantime the treatment consisted of instillations of atropin, an ice-bag to the eye, and morphin enough hypodermatically to make the pain bearable. He passed a restless night and consented to enucleation the next morning.

Examination of Enucleated Eye.—Section of the enucleated eyeball disclosed the following conditions: Scar of the cornea in the superior quadrant; a round hole in the iris just behind the scar; less cataractous, vitreous completely disorganized. In the inferior quadrant of the ciliary body there was a black object about 3 mm. long by 2 mm. wide. This turned out to be the bit of steel which had oxidized so that the outer shell came away like charcoal, leaving a solid nucleus about one-third of the original size.

Remarks.—It seems remarkable that a foreign body could have lain in the ciliary body, of all places, for seven years before giving rise to marked symptoms.

A CASE OF TETANUS TREATED BY INTRA- SPINAL AND INTRANEURAL INJECTIONS OF ANTITOXIN.

E. DUNSTER KREMERS, M.D.

HOLLAND, MICH.

The following case of tetanus, cured by the antitoxin treatment, is reported as an addition to the list of those already published as treated by this method:

Patient.—J. V. Z., aged 32, male, American, married.

History.—On Nov. 23, 1905, while working near the barn, the patient stepped on a rusty nail, which penetrated the left foot for a depth of about three-quarters of an inch. The wound bled freely. It was dressed with an external application of one of the common clay and glycerin poultices and healed without any trouble. On December 1 the man worked out in the field in cold weather and became thoroughly chilled. He soon began to complain of stiffness in the chest, which increased and spread to the back, legs and jaw. This was on the ninth and tenth days after the injury, and the stiffness was thought to be due to rheumatism. On December 3 and 4 he noticed that he had great difficulty in eating and that this trouble was growing worse. On December 5 he passed what he describes as a terrible night. He suffered repeated severe convulsions and was drawn back in opisthotonos.

Treatment.—When seen by Dr. E. De Spelder at 5 a.m. he was almost exhausted and was given morphin, gr. 1/4, hypodermically. He was seen again at 11 a.m. and his condition was about the same. At this time Dr. H. Kremers saw him

and gave morphin, gr. 1/2, hypodermically, and antitoxin, 2 dr., subcutaneously. The man's temperature was 100 and pulse 100. I saw him first at 5 p.m. on that day. He was sitting up in bed in general rigidity, jaw almost locked and temperature 101.5. Under chloroform anesthesia I introduced a needle into the spinal canal under the third lumbar vertebra and injected two drams of antitoxin. One dram was also injected into the thigh over the sciatic nerve. He was given by rectum chloral gr. xxxv, potassium bromid gr. xx. After this he slept for three or four hours and was kept quiet all night with morphin and large doses of chloral and bromid, which he swallowed through a soft rubber tube.

Course of Disease.—December 7 the jaw was a little stiffer. At 3:30 p.m., under chloroform anesthesia, I exposed the left sciatic nerve high up under the gluteal fold. The nerve was easily found and injected with 30 minims of antitoxin. A silk ligature was passed under the nerve to facilitate finding it and the wound partially closed. The wound in the foot, which had healed, was incised, disinfected with carbolic acid and iodin, equal parts, and packed with iodoform gauze. At 8 p.m., after moving the patient in bed, he went into a severe general convulsion with marked opisthotonos, cyanosis, cessation of respiration and fluttering heart. He was at once given chloroform and kept anesthetized until a hypodermic of morphin, gr. 1/2, had time to take effect, and then he was kept stupid the entire night.

On December 8 the patient had many small spasms, but no more severe ones. Placing a thermometer in the axilla or the drinking tube to his lips would bring on a spasm. During the day his temperature went up to 101.5 in the axilla, but he was kept quiet under drugging. At 5 p.m. the sciatic nerve was re-exposed and injected with 30 minims of antitoxin. A large amount was also injected into the foot. During the night the pulse became unsteady, running up to 135, and at the same time respirations went down to twelve to the minute.

On December 9 the patient was chloroformed once more and the nerve re-exposed. It was intended to inject the nerve, but when brought out of the wound it appeared very red and there was a piece of the sheath a half inch in diameter which had been torn away. On this account, fearing to injure the nerve, and since the patient was not growing worse, the antitoxin was injected into the tissues.

From this time on the condition steadily improved, although the spasms and trismus continued for several days, gradually growing less frequent and less severe. He was kept as still as possible in a darkened room and given morphin, chloral and bromids to keep him quiet. The jaw could be separated only a quarter of an inch, but the patient could be fed with a soft rubber tube. He drank large quantities of milk and water. The temperature slowly dropped with the trismus and rigidity, and on December 25 he was out of the house. The wound in the thigh healed rapidly and there was absolutely no disability in the leg except that the rigidity was slower to disappear from that side.

This case may be regarded as a rather subacute one, as the symptoms were slow in coming on and the jaw was not completely locked. It is hard to say, therefore, just how much influence the antitoxin had in the cure, but the condition was growing worse at the time the injections were first given and it is very probable would have gone on to death. The cases reported by Rogers' go far to show that antitoxin will cure tetanus if used in the manner he describes, even if used without any other treatment, and this case may be added to the list as recovering under the same treatment. As pointed out by Rogers, the chloroform is an important part of the treatment, as it reduces, for a time, the patient's excitability and relieves him of a great deal of his suffering. Chloral, also, in this case was found to be more effective in reducing the number of spasms than morphin. This case also shows that there is no great danger in the treatment itself, because, even though the nerve appeared deeply injected and wounded, there was neither pain, numbness nor paralysis in the affected leg. The treatment was all done in the patient's farmhouse, and this shows that it is an easy matter to carry out.

SATURDAY, MARCH 10, 1906.

THE FREE DISPENSARY EVIL.

Some time since we mentioned the lack of control of free dispensaries in almost all the states. We referred to the fact that New York had made an attempt to regulate dispensaries, but that the law passed in that state had been aimed primarily at the abuse of free clinics by well-to-do patients and that it only incidentally affected the more important question of the character of medical care furnished in free clinics.

This law has now had six years' trial, and at a recent meeting of the New York County Medical Society, held in New York City, the working of the law was reviewed by physicians and by members of the State Board of Charities and of the City Charity Organization Society. The report of the conference is interesting and enlightening from several points of view. In the first place, it seems to be generally conceded that the law has not attained the object for which it was framed, namely, "to remove the dispensary evil, which was commonly held to be the unrestricted multiplication of dispensaries and the indiscriminate bestowal of medical charity alike on the well-to-do, the self-supporting and the indigent." That the law has failed to remedy this the lay speakers, officials of charitable societies and inspectors for the state board make clear, although there is an attempt on the part of some dispensary physicians to claim that the evil has been lessened. On the other hand, it appears to be undeniable that, to a very great extent, the secondary object of the law has been attained. The licensing, inspection and control of dispensaries by the state board, according to the testimony of laymen and physicians alike, seem to have resulted in great improvement in the conduct of these institutions. It may be well to review briefly the provisions of the law in these respects.

The New York law requires all dispensaries to be licensed by the State Board of Charities. No dispensary may be opened unless it can be shown that there is need for such an institution in that locality and that when it is established it will be properly maintained. Suitable buildings must be provided, drug stores or tenements may not be used, seats for all applicants must be provided, cleanliness must be maintained, and a matron or female nurse must be present at all gynecologic examinations or treatments. The apothecary must be a licensed pharmacist or a medical graduate. Regularity of service is insisted on and also strict rules regarding

the isolation of contagious diseases. The board is empowered to revoke the license for cause, and has done so when necessary.

These provisions are certainly not unreasonable and it should be possible to enforce them. That New York has succeeded in so doing is evident by the reports read at this meeting.

In 1899, previous to the passage of the bill, dispensaries were in operation in tenement houses, drug stores and dilapidated old buildings and shanties. One, which reported treating 48,000 patients annually, was conducted in a wooden structure 12x20 feet and 8 feet high. In another water for physicians and patients was brought in a bucket from the next building. The last report of the board showed that 109 out of 119 dispensaries inspected were found in location and equipment to meet the requirements of the law. There has been an actual diminution in the number of dispensaries in spite of the steady increase in New York's population. In 1899 there were 136 dispensaries, in 1904 only 119, although the population of New York City has increased 150,000 annually during that time. In the matter of the proper conduct of gynecologic clinics, the keeping of records, and the regularity of attending physicians, the board reports decided improvement.

Undoubtedly, then, the law has been of marked benefit in raising the character of medical care in free dispensaries, and from this point of view it may be held up as a model to other states. But why should it have failed in remedying the evil for which it was specially framed? The answer is interesting, for it seems that while the medical profession was responsible for the framing of the law and is, of course, the chief sufferer from the abuses which it sought to abolish, it is the medical profession which defeats and nullifies it. Practically no genuine effort is made to weed out from a dispensary clinic the patients who probably are able to pay a physician's fee. Physicians in charge of dispensary clinics take pride in having a large number of patients on their days. Moreover, the well-dressed, prosperous-looking patient may prove to be the most interesting case of all. Hospital superintendents are quoted as saying that if they should restrict the dispensary cases to those who are clearly too poor to pay a physician the clinics would be so reduced that it would be impossible to retain the best specialists on their staffs. Dispensary registrars report that any attempt to use strictness in the admission of applicants meets with disapproval from the physicians. There is another motive sometimes encountered in privately conducted dispensaries, namely, the pecuniary gain represented by even a very small fee. Dr. G. C. Sturges mentioned instances of dispensaries charging a ten-cent fee which made from \$1,200 to \$3,000 a year.

Undoubtedly the exclusion of unworthy applicants from free clinics is a difficult if not an impossible task. What is to be the standard of "worthiness?" Any at-

tempt to decide on a patient's standing by his clothing, general appearance, intelligence, etc., ignores the fact that the experienced beggar always knows how to dress and act for the part. Dr. E. Le Fevre reported investigating personally thirty-five intelligent, well-appearing applicants for free care who all proved worthy, being people who had already paid their physicians all they could afford and yet needed long courses of treatment. Many a general practitioner is obliged to send to a dispensary patients of his own who need treatment by specialists for which they could not pay.

Then there is the question of dispensaries maintained for teaching purposes in connection with medical schools. Those connected with such schools are seldom anxious to limit the number of patients attending. Moreover, it would seem as if patients visiting such dispensaries and allowing themselves to be used for purposes of demonstration should hardly be regarded as free cases, for in a sense they pay for their treatment.

When we protest against the "abuse of the free dispensary" it is well to remember that we are ourselves chiefly to blame for this abuse, and it would be foolish for us to seek for a remedy through legislation until we are prepared to obey the law after it is passed.

PASSIVE CONGESTION IN THE TREATMENT OF INFECTIONS.

It is probable that in the treatment of many diseases the physician will never be more than the assistant of Nature. A two-fold tendency is to be seen in the therapeutics of recent years, on the one hand an effort to replace some of the older substances by less toxic products of chemical synthesis, and on the other a decided effort to utilize physical therapeutics. Both tendencies are in principle good, but both may be abused. Physical methods especially tend to act by encouraging or hastening natural processes of cure.

Among the advocates of certain forms of physical therapeutics must be mentioned the German surgeon, Bier, who for years has been extolling the value of passive congestion in the treatment of chronic joint affections. A little over a year ago this observer published an article in which he recommended the use of passive congestion in acute infections also. Such conditions as pararitium, furuncles, suppurative tenosynovitis, and acute osteomyelitis were suggested as being amenable to this form of treatment. The methods to be employed were essentially those previously described in the treatment of chronic affections. When the infection was localized in an extremity an elastic bandage could be used, if very restricted treatment was desired; or if the disease was on the trunk or head, a suction apparatus of glass with a rubber bulb exhaust was employed. As in previous articles, Bier laid stress on the necessity of a red hyperemia in the treatment of these cases. A complete stoppage of the venous circulation, with the resulting blue hyperemia, is regarded by him as productive of more harm than good.

Numerous articles have appeared in the past year¹ which support Bier's contention that in passive hyperemia we have a valuable means of combating acute infections. Recently Colley, Herhold and Mindes² have published commendatory articles. The reports show that certain forms of acute infection are more amenable to this treatment than others. In pararitium the application of the rubber bandage seems to be followed in most instances by rapid disappearance of the pain, a smaller incision is necessary (passive hyperemia does not take the place of incision), and the time of healing is materially reduced. Furuncles also seem to be especially suited to this form of treatment; when incision is necessary it need be very small, and if this form of treatment be instituted early enough the process may often be cut short. In phlegmons, particularly those communicating with tendon sheaths, smaller incisions are needed, packing is dispensed with, and in most cases the resulting limitation of motion seems much less than under ordinary surgical methods. In cases of osteomyelitis recovery frequently occurs without operation, and those patients operated on have a shortened period of illness. According to Colley, the method of treatment has a great future in the treatment of certain chronic forms of skin disease, a fact which he seems to have discovered accidentally in treating an individual who suffered from an infection complicating a chronic eczema.

The method of action of this form of treatment is of interest. It certainly does more than merely dam back the venous blood. According to Bier, the lymph stream is also interfered with during the period when the hyperemia is maintained. When the constricting band is removed, however, there is a great increase in the circulation of both blood and lymph. According to Noetzel, the fluid which is present in an artificially produced edema, such as Bier's method induces, is very strongly bactericidal. It is probable, too, that the simple dilution of toxins by the edema fluid plays a part in the process, and that the presence of leucocytes in the fluid is also a factor. The method is then simply a way of assisting Nature; it causes an increase in the flow of lymph, a condition which, as Wright has elsewhere shown, is of great importance in infections, inasmuch as it allows bacterial toxins to get into the circulation and to stimulate the formation of antitoxins. The inflammatory edema which Nature produces doubtless has much the same effect as the artificial edema produced by Bier's method, but once it has taken place there is practically no circulation in the fluid such as is produced by the intermittent production of passive congestion. Hitherto this method of treatment has not been adopted to any extent by American physicians, though the published accounts of its value are certainly encouraging.

1. See abstracts in THE JOURNAL A. M. A., April 1, 1905, p. 1075, and also pages 471, 473, 550, 621, 625 and 691 of the current volume.

ANEMIA IN PORTO RICO.

The peculiar and pitiful anemia in Porto Rico is caused by hook worms or *uncinaria*. "Porto Rican anemia" is simply another term for *uncinariasis* or *ankylostomiasis*. Physicians in northern parts see so little of this disease in their practice that it is at first a little difficult for them to grasp the extent, the significance, and the misery of this disease in Porto Rico and other tropical countries.

In March, 1904, a commission was appointed for the study and treatment of anemia in Porto Rico, and reference has been made in these columns to the results of its work, which was deemed of such importance that the Legislative Assembly in 1905 appropriated \$15,000 to continue the commission (Igaravidez, King, Bashford). The preliminary report of this commission, covering the period from June 1 to November 30, 1905, is at hand. A brief glance at some of the phases of its work will show the benefit practical methods based on scientific knowledge may bring to human sufferers in countries like Porto Rico.

The commission organized a central station and several substations for the microscopic diagnosis and the treatment of patients with *uncinariasis* and for the instruction of the people as to the nature of the disease and the means of its prevention. In all 18,865 patients were treated, 84+ per cent. were cured or practically cured (several hundred cases being still under treatment); only 33+ per cent. of the total number died.

Thymol seems to be the favorite drug and the commission expresses the belief that five consecutive doses of thymol or beta-naphthol are "sufficient, usually, to bring the patient, if not to a technical cure, at least to the assurance of a practical cure." The specific treatment of "Porto Rican anemia" is thus definitely established. "The long list of 'sure-cure' patent iron pills, powders, and blood and nerve restorers, so dearly paid for by the unfortunate and credulous 'jébaro,' paid for, it should be remembered, from the earnings of a class said to be starving in poverty, is a list too long and too disgusting to contemplate without anger and a sense of shame." The use of iron as a *sine qua non* in the treatment of postuncinarian anemia is being abandoned in Porto Rico, and the vendors of patent ferruginous tonics should cease baseless exploitation of their wares.

According to the observations of the commission, 99 per cent. of all who harbor *uncinaria* receive the infection through the skin, usually of the bare feet, from contact with soil or water loaded with larvae. "Ground itch" or "Mazamorria" is the first sign of infection and, if repeated or severe, *uncinariasis* may follow, and the patient in his turn becomes a menace to public health. The coffee plantations offer most favorable opportunities for infection of the soil by feces. Based on considerations, most briefly indicated, of this nature, the commission holds that success of the campaign against *uncinariasis* in Porto Rico involves the treatment of all infected persons

in order to "render innocuous the feces of thousands who will continue to inoculate the soil in spite of prayers, lectures, advice, coaxing and even the prohibition imposed by the law." The wearing of shoes and the provision of latrines or even pits, adequately supervised, for defecation are additional measures that must be pushed to the utmost. We see that *uncinariases*, now that we know the nature and the manner of spread of the disease, has become a preventable (one is tempted to say, easily preventable) disease. The magnificent work of the Porto Rico commission must be continued and extended.

BUSINESS METHODS AND PROFESSIONAL MORALS.

Recent investigations into business methods have unearthed a degree of corruption which is almost incredible to those unacquainted with the conditions and which have been destructive of confidence in the integrity of the modern commercial world. With no intention of self-righteous boasting and no desire of condoning unjustifiable practices, we are proud to believe that the medical profession is freer from graft than any other equal number of men in the ranks of a profession or business. And this is as it should be. The relation of a patient to his physician is a most intimate one, and one in which implicit confidence is the very foundation of the relationship. The patient puts his life and his health unhesitatingly in his physician's hands; he feels that even if his physician lacks skill or needs assistance in an emergency he at least is honest and will do what seems best for the patient's interests. But it would be remarkable, considering the almost universal prevalence of "graft," if some doctor did not abuse this relationship. This he does in the so-called division of fees, a species of graft that we are compelled to acknowledge does exist, although undoubtedly it is extremely rare. While there is a probability of any of this kind of business going on it demands that we give thought to the matter. It is something we can not afford to treat in an ostrich fashion.

In his retiring address as president of the Syracuse Academy of Medicine Dr. T. H. Halsted brought out in a most forceful way some important truths with regard to this evil. He pointed out the importance of the position of trust and confidence occupied by the members of our profession to the public, and referred in a forceful manner to the abuse that some had made of the privilege in the species of graft referred to above. He said that the dividing of fees, without the patient's knowledge, is a most dishonorable transaction. If the fee division be done with the patient's knowledge then there is no dishonesty in the transaction. The patient has relied on the advice of his physician in selecting the most competent consultant. He assumes that his physician knows the best man, and without question accepts his advice. Did he know that his physician was considering, in addition to the con-

sultant's medical qualification, the question as to how much of the fee he was to receive the patient would probably feel that his doctor's advice might not be wholly disinterested.

The family physician should stand between the surgeon and his patient, looking after the latter's interests and using his judgment as to the necessity for an operation. He can not permit his judgment to be influenced by financial consideration, and if he does he betrays the patient who has placed his confidence in him. A man who permits himself to accept from such a surgeon, consultant or specialist a division of the fee or a commission without his patient's knowledge inflicts an injury on his character which sooner or later will tell on his reputation, because those things which cause a moral deterioration have a way of showing themselves unconsciously. Now, what of the consultant who divides the fee or pays the commission? To begin with, he is taking an unfair advantage of his colleagues, competing with them, not on a basis of professional skill, character and attainments, but he is secretly actually paying money to physicians to have their cases referred to him and diverted from his more honorable colleagues who expect recognition on professional merits alone. This may be a shrewd method of getting lucrative practice, but it has its disadvantages. Such a man thinks too much of his fee, his judgment gets warped, and before he knows it he finds himself in the habit of wondering how much money can be gathered from the patient, rather than what is best to do for him. The physician who has called him in consultation must frequently be in doubt as to how much reliance can be placed—with safety to the patient—on his advice. Each—the payee and the payor of the commission—loses confidence in the other. The patient would undoubtedly question the advice did he know of the method pursued—and some patient will find out—some time.

He who adopts this "graft" makes of his profession a dishonorable business, with the inevitable result of developing his money-making instincts at the sacrifice of professional skill, acquisitions and judgment, and it can be but a matter of time until his reputation—one of the best assets—is gone, and he finds that while he has been getting a practice, his slower, more honest competitor has been building on a surer foundation and has been establishing a reputation. The one has been deteriorating in his moral fiber from the beginning, the other has been gaining strength. So that, in the long run, it will be found that in our profession, as everywhere else, the old aphorism that "honesty is the best policy" still holds true. All surgeons, or practitioners of specialties, are only too well aware of the truth of these statements.

No doubt this system of graft had its origin in the existence of an unfair discrepancy between the size of the consultant's fee and the fee of the faithful physician and general practitioner. With all due allowance for the value of superior ability and experience and the high cost of long years of special training, some consultants charge

fees which, compared with the fee of the general practitioner, must seem excessively large. But this has nothing whatever to do with the matter, or, if it does, **let the division be made, but with the patient's knowledge.** It is certain that many physicians are not receiving the income which they should considering the irregular hours and nerve wearing work in which they are engaged. Yet the best way to increase the income is not through practices of the kind mentioned, but by a united effort to raise prices so that a living income may be earned. The advantages of a united medical profession must be evident to all in this as in other connections and we hope that by such united effort a better financial condition may be brought about, and this without the sacrifice of honor in any respect.

CANCER RESEARCH.

Investigations into the origin of cancer and into other mysteries connected with this obscure disease are being earnestly prosecuted in all parts of the civilized globe. Edinburgh has contained for some time investigators eminent as would-be solvers of the cancer problem, among these may be mentioned Russell and Stiles.

The latest contributor to the subject is Dr. John Beard,¹ lecturer in comparative embryology in the University of Edinburgh. From his study of fish he concludes that aberrant germ cells exist in all parts of the body, each of which, under unknown conditions, may give rise to a cancer, which is thus essentially an asexual structure. Further, Dr. Beard asserts that even in the development of man himself there is a brief but not insignificant stage, during which an asexual structure is produced. In short, that "alternation of generations" (alternately sexual and asexual) which is so familiar in many of the lower animals and plants, has not been entirely suppressed. Dr. Beard is of the opinion that he will discover the cause leading to the arrest of development of the asexual structure. If, as he surmises, a malignant tumor be but another asexual structure, it might be controllable by whatever cause controls the normally produced asexual structure. Dr. Beard thinks that he has, to a certain extent, been able to do this. Rather more than a year ago he demonstrated that in the case of the fish the arrest of development of the asexual stage and the disappearance of the asexual structure coincide with the commencement of the activities of the pancreas. If the secretion of the pancreas be absent the asexual structures of the fish do not degenerate. The constituent in this secretion with which we are most familiar is trypsin. Dr. Beard believes that in mice with experimental cancer he has been able to arrest the disease by means of trypsin. Relatively large doses were given by inoculation, without visible injury to the body cells, while the cancer cells simply crumbled away. Trypsin has already been administered in very modest doses

1. British Med. Jour., Jan. 20, 1906; abstract in THE JOURNAL A. M. A., Feb. 17, 1906, p. 544.

to human patients, the effect being an apparent prevention of the recurrence of cancerous growths after surgical operation. Dr. Beard, arguing from his studies in embryology alone, holds the view that trypsin will be found to be perfectly harmless so far as the living body cell is concerned. The argument in favor of the value of trypsin in cases of malignant tumor is that the living body is a sexual product, and that whereas it has a destructive action on asexual products, it has no power whatever over the cell products of sexual generation. Dr. Beard terms trypsin the architect of the soma.

So many assertions in recent years have been made of cures for cancer, many, if not most, of which have been scandalous and unblushing frauds that men of science are now very chary of accepting any such statements. Naturally, until the cause of malignant growths is discovered, it would be idle to expect a rational and radical cure. There can be no doubt, however, that more or less satisfactory progress is being made in regard to cancer research, and at any rate the deductions of a man of the scientific rank of Dr. Beard are entitled to respectful consideration. It is to be hoped that still more encouraging reports will be forthcoming from the Edinburgh laboratories in the near future respecting Dr. Beard's investigations.

"THE COMING CONQUEST OF CANCER."

The interesting embryologic studies of Beard and his deductions therefrom, anent cancer, referred to above, have been utilized as the basis for more or less sensational and overdrawn statements in the lay press. An article in *Harper's Weekly*,¹ by C. W. Saleeby, M.D., concludes with the following announcement: "It seems more than probable that in trypsin has been discovered, for the cancer cell, that specific poison which must exist for every cell. Only the philosophic few could have guessed for a moment that Dr. Beard's long and famous researches would ever enable him—as they would, indeed, appear to have enabled him—to place in the hands of the physicians a veritable cure for cancer."

Now, do the facts at hand really justify this startling conclusion? Beard holds that in fishes aberrant germ cells exist in all parts of the body, and reviews in a somewhat more definite and modified form Cohnheim's hypothesis of the origin of tumors, more particularly cancer, in persistent embryonal cells. In fish the cells in question disappear as the pancreas assumes its physiologic activity, hence the suggestion already acted on to use trypsin in human cancer. As yet, however, we have no really conclusive evidence that trypsin has any decisive effect on human cancer. It is not claimed, even by Saleeby, that trypsin has been shown to prevent the return of cancer after operative removal. There is no record of the cure of human cancer by trypsin. In experimental cancer of mice trypsin is said to cause the tumor cells to die and to crumble away, but it is plain that many more successful experiments are necessary at

the hands of various investigators before it can be concluded definitely that trypsin cures cancer in mice.

We see that while the results obtained by Beard may warrant the continued study of the effects of trypsin on cancer, there is at present no basis whatsoever for the inference that a veritable cure for human cancer has been discovered. Under these circumstances it would have been more prudent, to say the least, on the part of Saleeby to have refrained from making statements in public print that are not readily differentiated from those "premature, outrageous, and, indeed, brutally cruel announcements which constantly infest the press," and which he himself condemns.

PUBLIC INSTRUCTION IN SEXUAL HYGIENE.

If the knowledge possessed by the medical profession as to the prevalence of the venereal disorders and their disastrous consequences, especially to the innocent wives and mothers of the country, and too often to their offspring, was possessed by the public generally, the evil-named could not continue in their present prevalence and virulence. We warn the public freely against small-pox, we create almost a panic in regard to the "great white plague," but we actually cultivate ignorance in regard to a class of diseases which, while not always directly fatal, are directly and indirectly responsible for a vast proportion of the existing human misery. There is no doubt that with a patient and intelligent agitation of this subject by our profession, with the end of securing a more general knowledge on the part of the public of the facts, we could accomplish a vast amount of good and possibly eradicate the evils to a very great extent. A great change has taken place in the last few years, and the sign of the times is that the ban of secrecy is being removed and that light is to be shed on this subject so long shrouded in darkness. Sociologic workers are taking up the problem in earnest, and their co-operation will make effective the awakening for which the medical profession has long appealed. For example, *Charities and the Commons*, a periodical whose views on subjects more or less closely related to medicine we have often had occasion to quote with approval, publishes in its issue of February 24 communications from several prominent medical authorities on sexual hygiene and the necessity and propriety of the instruction of the public, especially the young. There need be no sacrifice of modesty or propriety if the effort is properly conducted. There are many ways in which the instruction can be given by parents to the inquiring child or by teachers and others to the still ignorant adolescent. We must remember that information is sought and secured on these subjects, and there is almost a certainty that what may be obtained from the usual sources is liable to be corrupting and dangerous both from a physical and a moral point of view. A recent writer¹ says: "Even the air of mystery that surrounds this subject when it is not frankly treated is a source of danger. For it stimulates the imagination, drives to clandestine sources of information, and tends to precocious stimulation of the sexual organism." The medical profession has much to do with the creation of a proper public opinion on this subject.

1. March, 3, 1906.

1. Prof. George A. Coe, "Education in Religion and Morals."

It is from physicians that the public has to obtain its facts, as is recognized by the sociologic journal here referred to, and it is only by the dissemination of correct information that we can combat one of the greatest social evils of all times.

THE STATURE OF THE JAPANESE.

The Japanese feel that their comparatively diminutive stature is a national humiliation, according to the reported statements of Surgeon-General Takaki of the Japanese navy. He attributes their smallness of stature to centuries of imperfect nutrition, and believes that by proper dietetics they can soon attain the full stature of the European races. Already, by change of diet, a marked improvement has been made in the Japanese navy, and he thinks that an equal effort will increase the stature of the general population. This is following Western ideals with a vengeance; notwithstanding their diminutive stature the Japanese in war have proved themselves to be fully the equals of at least one European nation, and it is perhaps a question whether their smallness might not have been an advantage to them under the conditions of modern warfare. As a correspondent of *Nature* points out, a very appreciable percentage of the Russian fire must have been ineffective as compared to that of the Japanese on account of the difference in size of the respective human targets. Still, if the Japanese wish to be large—and size has some advantages—no one can object. The main question is whether economic conditions in Japan will afford the essentials for such general dietetic alterations as are called for by the proposed experiment.

Medical News

ILLINOIS.

New Hospital.—The Methodist Memorial Hospital, Mattoon, will be formally opened and dedicated March 17.

Smallpox.—A case of smallpox was discovered in the Illinois State School for the Blind, Jacksonville, February 24.—The mayor of Colfax has ordered the postmaster to cease forwarding any mail from Colfax in order to check the spread of smallpox in that place.

Physician Gets Verdict.—A jury in the Circuit Court of Logan County brought in a verdict for \$350 in favor of Dr. Hiram L. Cosby, Lincoln, against Sheriff James White of Logan County for professional services in saving the life of a man accidentally shot by the sheriff last year.

Old Offenders Brought to Time.—Mrs. E. R. Liens of Decatur, an old-time violator of the Illinois medical practice act, has been compelled by attorneys for the State Board of Health, to make a settlement for her violations, including the payment of all costs of prosecution, and to enter into a written agreement to discontinue practice. Mrs. Liens conducted a bath and massage institution in Decatur and manufactured "Lien Diphtheria Cure." From time to time she undertook the nursing of diphtheria cases, using and applying her own remedy. Suit was brought against her at the instance of the State Board of Health in a justice court, but this suit was decided in favor of the defendant. The board promptly appealed and hearing was set for the January term of the Mason County Circuit Court. The case was settled only after a number of futile efforts of the defendant to secure continuance.—After several months of constant effort to bring justice on him, the State Board of Health has finally been successful in its suit against George B. McClellan, who was advertised extensively in Illinois as "Diamond Dick," the Indian healer. Recently authorizations for McClellan's prosecution had been issued in McHenry, McLean and Marshall counties

and in these counties suit was commenced, but the defendant in each instance escaped before service could be secured on him. About the middle of February he was found to be plying his trade in Adams County, in the vicinity of Quincy. He was caught and prosecuted at Golden, and a judgment for \$122.85 was secured against him. Being unable to pay the fine, the defendant gave a bill of sale for his eight trunks and other paraphernalia to avoid going to jail. "Diamond Dick" is an old offender. He was fined \$100 and costs in Peoria in 1901, and similarly in 1903 in Marengo, where he spent some time in jail. The energetic action of the State Board of Health has made practice impossible, and he now finds himself deprived of his goods and with cases pending against him in various counties, in which he will be promptly prosecuted if he appears.

Chicago.

Smallpox.—A case of smallpox was brought into Chicago from the West, February 27. The patient was a railway porter. No other cases have developed.

Laryngologists Meet.—A successful meeting of the middle section of the American Laryngological, Rhinological and Otolological Society was held in the Northwestern University building, February 26.

More Funds for Hospital.—J. Oden Armour has given \$25,000 toward the \$140,000 required for the new George Smith addition, St. Luke's Hospital. Of the required amount \$80,000 is at present in the treasury.

Hospital Plans Abandoned.—It is reported that the Iroquois Memorial Association has abandoned its plans for the establishment of a hospital to commemorate those who perished in the Iroquois Theater fire, on account of lack of interest in the project.

Needs New Building.—The Chicago Eye, Ear, Nose and Throat College contemplates the erection of a new building to accommodate the increasing needs of the institution, to cost \$75,000. At the annual meeting the old board of directors was re-elected.

Deaths of the Month.—February furnishes the lowest mortality rate recorded in the history of the city, 14.07 per 1,000. The total deaths number 2,217, and among the principal death causes were: pneumonia, 413; consumption, 239; nephritis, 161; heart disease, 163, and violence, including suicide, 159.

Deaths of the Week.—The total deaths from all causes for the week ended March 3 were 563, equivalent to an annual death rate per 1,000 of 14.32, a lower death rate than for the previous week or for the corresponding week of last year. Pneumonia led the death causes with 111, followed by consumption with 63, nephritis with 43, violence, including suicide, with 36, and heart diseases with 32.

Recommends International Vital Statistics System.—In THE JOURNAL, January 27, page 283, in the item concerning the report on the Chicago department of health statistics by the committee of investigation, which was appointed for the purpose by the Chicago Medical Society, the impression is given that the committee's approval covered all the methods of the department. The committee did not favor the system of classification in use by the department and recommended the international system of classification instead.

IOWA.

Inebriate Hospital Full.—The new State Hospital for Inebriates, Knoxville, which was opened early in February, is now filled nearly to the limit, and many applicants are waiting for admission.

Magnetic Healer Convicted. D. F. Miller, a well-known healer of Waterloo, who was arrested for practicing surgery, medicine and obstetrics without state license, has been found guilty as charged.

New Hospitals.—A German-American Catholic hospital is to be erected in Waterloo this year, to cost about \$70,000.—The newly constructed cottage for men at the Clarinda State Hospital was opened early last month.

Made Insane by Drugs.—Dr. Hiram L. Getz, Marshalltown, has been adjudged insane and committed to the Independence State Hospital. He has been suffering from diabetes for about a year and has become habituated to the use of drugs.

Will Not Admit Consumptives.—The State Board of Health, at a recent session held in Des Moines, adopted an amendment to its rules by which no teacher or child afflicted with tuberculosis is to be permitted to teach or attend school in the state.

Damages Against Physician.—In the case of Reynolds vs. Dr. Thomas U. McMann, Waterloo, in which \$10,000 damages

were claimed on account of alleged malpractice, a verdict of \$5,000 for the plaintiff was returned February 16. Dr. McManus' attorneys have asked for a new trial.

Personal.—Dr. Even F. Cowger, Riverton, has moved to Monte Ne, Ark. —Dr. Amos J. Thornber, Burlington, has been made president of the Des Moines County Medical Society, vice Dr. Nathaniel McKittrick, resigned. —Dr. Samuel W. Moorhead has been made postmaster of Keokuk.

Southwestern Association Meeting.—At the annual meeting of the Southwestern Iowa Medical Association, held in Creston, February 10, about sixty were present, and the following officers were elected: President, Dr. William R. Whitnall, Hastings; vice-president, Dr. Lynch, Greenville, and secretary and treasurer, Dr. Joseph P. Clayhough, Creston.

Boy Healer a Practitioner.—In the case of the State of Iowa vs. J. G. Gallagher, "the Minnesota boy healer," charged with illegal practice of medicine, the demurrer to the indictment was overruled by the court, who stated that "a person shall be held as practicing medicine who publicly professes to heal or cure diseases or ailments of the human body if such profession be made under such circumstances as to indicate that it is made with a view of undertaking to cure the afflicted."

KENTUCKY.

Injured in Explosion.—Dr. R. E. Gatz, professor of pharmacy at the Hospital and College of Medicine, Louisville, was seriously injured by the explosion of a test tube in the laboratory, February 24.

Physician Wins Suit.—In the suit of Mrs. Kate L. McCullough vs. Dr. Elias S. Frey, Louisville, for \$5,000 damages, alleged to have been due to an improper prescription, the jury returned a verdict for the defendant January 24.

Midland Physicians Meet.—The Kentucky Midland Medical Society met at Midway January 15 and elected Dr. William B. McClure, Lexington, president, and Dr. Charles W. Kavanaugh, Lawrenceburg, vice-president, and Dr. J. Harry Arnold, Versailles, secretary-treasurer.

Fires.—Fire in the Odd Fellows' Building, Smith's Mills, February 8, caused \$300 damages to the office of Dr. Levin C. Royster. —On February 3 a disastrous fire occurred in Richmond which caused the loss of \$1,000 each to Drs. Thompson J. Taylor and J. G. Bosley.

Colored Physicians in Trouble.—In the case of the City of Owensboro vs. Dr. Walker, charged by Dr. Jeremiah M. Peters with assault in a quarrel over a vaccination, Dr. Walker was fined \$25, and during the progress of the trial Dr. Peters was fined \$3 for contempt of court.

New Hospital Staff.—The Good Samaritan Hospital, Lexington, announces the following hospital staff: Consulting staff, Drs. David Barrow and Thomas H. Kinnaird; attending staff, Drs. Frank H. Clark, James C. Carriek, Edward M. Wiley, Julian T. McClymonds, Walter O. Bullock, John W. Scott, Archibald H. Barkley, Thomas Holloway, Charles W. Morris, Joseph A. Stucky, N. Lewis Bosworth and Jefferson D. Kiser.

Tri-State Meeting.—At the meeting of the Central Tri-State Medical Society of Ohio, West Virginia and Kentucky, held at Catlettsburg January 20, the following officers were elected: President, Dr. George Marshall, Portsmouth, Ohio; vice-presidents, Drs. John D. Williams, Catlettsburg, Ky., and Albert S. Brady, Greenvy, Ky.; secretary, Dr. Smithfield Koffer, Ashland, Ky., and treasurer, Dr. Thomas W. Moore, Huntington, W. Va.

Personal.—Dr. Charles H. Todd of Owensboro has been elected president of the Daviess County board of health. —Dr. Clarence H. Vanght, Richmond, has been elected president of the Central Kentucky Medical Society. —Dr. Robert Rivers, Paducah, who suffered a severe burn of the right eye several weeks ago, has entirely recovered. —Dr. John V. Hayden, Salem, has been elected president, and Dr. Frederick G. La Rue, Smithland, secretary, of the Livingston County board of health. —Dr. W. Guy Eckman has been elected jail physician of Covington, vice Dr. James A. Davis. —Dr. J. Halpin O'Reilly, Louisville, is seriously ill with pneumonia. —Dr. Leslie Rudolph, Woodville, who has been critically ill, is improving.

MAINE.

Gift to Hospital.—An anonymous friend of the Knox County General Hospital, Rockland, has made his annual donation to the institution, to be used for the maintenance of the James A. Creighton memorial free bed.

Northern Maine Hospital Opened.—The Northern Maine General Hospital, Eagle Lake Mills, was opened for the reception

of patients January 15. The building contains forty rooms and three wards, and will have cost, when completed, about \$12,000.

Clinical Society Meets.—The Waterville Clinical Society held its annual meeting February 22 and elected the following officers: President, Dr. Edward W. Boyer; vice-president, Dr. H. E. Milliken; secretary and treasurer, Dr. Frederick C. Thayer, and business committee, the vice-president, secretary and Dr. B. B. Cragin.

Personal.—Dr. Herbert S. Sleeper, Lewiston, has been elected a member of the local board of health. —Dr. Bigelow T. Sanborn has been elected a member of the Augusta City Hospital corporation. —Dr. Milton C. Wedgwood, Lewiston, is seriously ill. —Dr. David S. Himmewell, Madison, who has been ill with bronchitis, is reported to be much improved.

Academy Election.—At the annual meeting and banquet of the Maine Academy of Medicine and Science, held in Portland, Dr. Clarence A. Peaslee, Bath, was elected president; Dr. Albion H. Little, Portland, corresponding secretary; Dr. Frank Y. Gilbert, Portland, statistical secretary; Dr. Gilman Davis, Portland, assistant secretary, and Bertrand G. March, Portland, treasurer.

County Society Meeting.—The twelfth annual meeting of the York County Medical Society was held at Biddeford, January 11. The following officers were elected: President, Dr. William W. Smith, Ogunquit; vice-presidents, Drs. M. Hubbard Ferguson, Biddeford, and Roland S. Gove, Sanford; secretary, Dr. Clarence E. Thompson, Saco, and treasurer, Dr. Harry L. Prescott, Kennebunkport.

Communicable Diseases.—Smallpox is still being reported in the eastern part of the state, the latest reports coming from Houlton, Cary and Lincoln. —Typhoid fever has appeared in the lumber camp and mill of S. P. Dean & Son Company, west of Dudley. The condition is rendered more serious by the fact that the camp is so far removed from medical aid.

A colored car cleaner for the Boston & Maine Railroad Co. at Portland was taken sick at his work at the Union Station, February 24. He was examined by physicians and found to be suffering from smallpox. He was removed to the detention hospital. —A case of smallpox was discovered in a lumber camp in the town of Ludlow this past week. The authorities were notified and the camp was quarantined.

MARYLAND.

Patent Medicine Bill. A new patent medicine bill, said to be satisfactory to the drug trade, has been introduced in the legislature.

Vital Statistics Bill. Favorable report has been made in the senate by the committee on sanitary conditions on a bill to enable the State Board of Health to collect vital statistics when local officers fail to collect them.

Tuberculosis Sanatorium Bill.—A bill has been introduced into the senate creating the Maryland Tuberculosis Sanatorium and making appropriations for its erection and maintenance. It requires the institution to be accessible by both railroad and water transportation, and places it under the control of a board of managers composed of the governor, the treasurer, the controller of the treasury, ex-officio, and six other persons, who shall be appointed by the governor. Of these six, two are to serve for two years, two for four years and two for six years—from May 1, 1906. Thereafter the governor is to appoint two members of this board, to serve for six years, biennially. They are to be chosen with a view to their intelligence, experience and character and without reference to ecclesiastical or party ties. The bill appropriates \$100,000 for the establishment of the institution, land and buildings, and \$25,000 annually for its support. It has the approval of the state tuberculosis commission and State Board of Health, and is backed by the medical profession.

Baltimore.

February Deaths. During February 23 persons died from whooping cough (which is quite prevalent), 10 from influenza, 119 from consumption and 177 from pneumonia.

Smallpox.—Seven cases of smallpox were reported during the week ended February 25; 8 patients, all colored, were sent to the city quarantine station from Baltimore County on the same day; 19 cases in all were reported in the city during February.

Addresses Delivered. Dr. Ira Reuben, president of the Johns Hopkins University, addressed the Johns Hopkins Alumni in New York City, March 2. —Dr. Howard A. Kelly spoke to 1,000 men at St. John's Church, Roanoke, Va., Febru-

ary 25, on "Purity of Manhood."—Dr. N. H. D. Cox lectured March 4 on "Missions in Africa," where he spent three years as a missionary.

Hospital Report.—According to the twenty-eighth annual report of the Presbyterian Eye, Ear and Throat Charity Hospital, 11,803 patients were treated in 1905; 10,605 of these being white. There were 7,012 eye, 2,348 ear and 2,443 throat cases. There were performed 1,392 operations on the eye, 166 on the ear and 750 on the nose and throat. Since the opening of the hospital 227,048 cases have been treated.

MICHIGAN.

New Hospital Soon Ready.—The new Lutheran Hospital of Bay City will be ready to receive patients April 1.

Personal.—Dr. W. Francis Ertell, Kalamazoo, has been confined to the house by illness.—Dr. Andrew P. Biddle, Detroit, is seriously ill with inflammatory rheumatism.

Patent Medicine Ordinance.—An ordinance to prohibit the free distribution of samples of patent medicines, drugs, ointments, pills, powders and pellets on the streets or from house to house in the city of Grand Rapids, was passed by the common council, February 19.

Smallpox.—Smallpox is still increasing in Gladstone, and several cases are reported among the employes of the Cleveland Cliff Iron Company, Kipling.—The disease has appeared in the vicinity of Calumet, and it is said that in the logging camps 200 men are at present under quarantine.

Banquet to Dr. Harrison.—A dinner to welcome Dr. Beverly D. Harrison, secretary of the Michigan State Board of Registration in Medicine, formerly of Sault Ste. Marie, to Detroit, was given by Dr. Fleming Carrow, February 21, at which a number of the prominent physicians of Detroit were present.

Trichinosis.—Dr. J. W. Gastin, chairman of the Bay City board of health, has located the source of the trichinosis infection which has caused more than thirty cases of illness and one death in the city, at a farm near Vassar, where the hog from which the infected meat was cut was purchased.

New Dean of the Dental Department.—Prof. W. D. Miller of the University of Berlin has been offered and has accepted the position of dean of the Department of Dentistry of the University of Michigan, Ann Arbor. He will come to this country and begin his work in 1907. Dr. Miller's researches on the bacteriology of the mouth and dental caries are well known. He is a graduate of the University of Michigan, but has been the professor in the dental department of the University of Berlin for twenty-five years.

NEW YORK.

Water for Long Island Towns.—The Citizens' Water Supply Company has made a contract to build a plant at Great Neck and supply that place and Thomaston with water. The entire plant will cost nearly \$100,000 and will have a capacity of 2,300,000 gallons a day.

Osteopaths Plead.—Osteopaths in large numbers attended the joint hearing on February 28 before the senate judiciary and assembly public health committees to plead for the passage of a bill establishing a board of examiners for osteopathic physicians. The measure was opposed by physicians from all over the state.

A Field Hospital. A bill was signed by Governor Higgins on February 26 providing for the organization of a field hospital to be attached to the headquarters of the national guard, to consist of one surgeon with the rank of major, three assistant surgeons, six field hospital sergeants, eight corporals, thirty privates, one musician and one cook.

Bills Proposed. A bill has recently been introduced into the legislature providing for a reservation on both sides of the Bronx River, from Kensico to Bronx Park. The reservation is considered necessary to prevent the pollution of the Bronx River by the towns to the north.—Another bill provides that "any person who by word of mouth or by written or printed circulars, messages, letters, documents, pamphlets, newspapers or magazine articles or publication of any kind, made, issued or circulated by him or by his authority, advocates or teaches the duty, necessity or propriety of putting to death by legal sanction or otherwise persons afflicted with an incurable disease because of their condition, is guilty of a felony."

Insanity Increasing.—According to the annual report of the state commissioner in lunacy submitted to the legislature, insanity is on the increase in this state. In 1892 there was one insane person to every 337 people in the community.

Now the ratio is one to every 299. The commission considers this condition grave, but says that the new cases last year were fewer than the previous year. There are 27,406 insane in the public and private institutions of the state and 6,000 insane are maintained in their own homes. In the state institutions the net increase last year was 499, the lowest in ten years. It cost the state \$4,593,477 to care for the insane last year. Improvements to insane hospitals cost \$838,000 during the year. There were 5,316 new cases of insanity developed last year, of which the state institutions discharged 1,442 as recovered and 1,257 as improved. The state hospitals for this year asked \$2,000,000 for netterments, but the commission has cut this to \$1,500,000. The legislature is asked to appropriate \$4,950,000 for the care of the insane this year. The commission expects that with the money available for improvements and additions to the state hospitals the overcrowding in these institutions will cease before the end of the year. The commission presents the first report to the state board of alienists, which is especially charged with the duty of returning to their homes alien lunatics who find temporary domicile in the state. This work was hitherto undertaken by the commission of the state hospital superintendents. Owing to the activity of the new board the state was relieved during the past year of 417 insane patients of the alien class.

Report of New York State Health.—The report of the New York State Department of Health for 1905 states that the most conspicuous feature of epidemic diseases has been the continued prevalence of cerebrospinal meningitis and the increase in its mortality. The disease was most prevalent in the maritime district and mostly in the borough of Manhattan. At the same time there was a moderate increase in the Hudson and Mohawk valley districts, and in the east central and the Lake Ontario and western districts. This, however, was anticipated, as it has been observed that a considerable local outbreak is often attended in subsequent seasons by much more widespread prevalence. Smallpox existed in a few places in the state during the year, but there were no deaths from it outside of New York City. The general mortality of the year was excessive, the spring mortality exceeding that of the summer; this was due chiefly to pneumonia and acute respiratory diseases, influenza being one of the chief of these. During the year rules were adopted requiring that certificates of stillbirths be filed in the State Bureau of Vital Statistics. These certificates showed that there were about 10,000 stillbirths in the state during the year. The death rate in the larger of the state institutions was 5.56 per 100, against 6.85 during the previous year. The report states that the registration of births is far from satisfactory, and that the most incomplete registrations are in the cities of Albany and Troy. The registration of marriages, while more complete than that of births, is not satisfactory, and the report advises the enactment of a law requiring the contracting parties to procure a marriage license from the county clerk of the county in which the marriage is to be performed. It is also recommended that for statistical purposes as well as for the safe keeping of original certificates of births, marriages and deaths in the state, all such certificates outside the city of Greater New York should be filed with the State Department of Health. The work of the bureau of sanitary engineering in conserving the water supplies of the state is also noted. The report states that the department should be better equipped to protect the water supplies of the municipalities of the state, thus enabling it to prevent epidemics of typhoid fever due to impure water. General investigations of sewage systems and of sewage disposal were made. New work is outlined and needed changes and improvements are suggested.

New York City.

Centennial Celebration.—At a meeting of the Medical Society of the County of New York, held January 22, it was voted to celebrate the centennial of the incorporation of the society by a dinner at the Hotel Astor on the evening of April 4.

Illegal Practitioners Fined.—In the Court of Special Sessions, January 11, Anthony Ofrias, a druggist of 382 Tenth Avenue, was fined \$250 for illegally prescribing for a fee.—John Justin, an osteopath, was fined \$100 for practicing without a license.

Hospital Dedicated.—Archbishop Farley dedicated the new St. Francis Hospital on March 1. It occupies the entire block bounded by One Hundred and Forty-second and One Hundred and Forty-third Streets, Brook and St. Ann's Avenues, and contains 400 beds.

Harvey Society Lecture.—The twelfth lecture in the Harvey Society course will be delivered by Prof. Theobald Smith of the Harvard Medical School at the New York Academy of

Medicine, March 10, at 8:30 p. m. Subject: "The Parasiticism of the Tubercle Bacillus and Its Bearing on Infection and Immunity."

Needs of Hospital.—The New York Society for the Relief of Ruptured and Crippled reports that in 1905, 963 patients, mostly children, were treated in the hospital, and that 44,157 treatments were given outside. The hospital is very much in need of funds and runs \$40,000 behind its permanent subscriptions every year.

Homes for Poor Convalescents.—Comptroller Metz urges the leasing by the city of the Manhattan Beach and the Oriental properties, including the hotels, for convalescent homes for the city's poor. The Austin Corbin estate, which owns the hotels, is willing to lease these two properties to the city for \$150,000 a year, or to sell outright for \$3,150,000.

More Physicians for Bellevue.—As the result of recent action taken at a meeting of the board of trustees of Bellevue and the Allied Hospitals, Bellevue will hereafter have four paid physicians in its receiving ward. They will receive a salary of \$600 annually, will serve four-hour tours of duty, and will probably be chosen from the internes of the hospital.

Hospital Economies.—A preliminary meeting of representatives of more than a score of hospitals was held recently with a view to effect economies on hospital management. It was suggested that the city take charge of the ambulance service and establish a system of receiving stations throughout the city, where patients might first be taken and then sent to such hospitals as were able to receive them.

Contagious Diseases.—There were reported to the sanitary bureau for the week ending February 24, 1,636 cases of measles, with 34 deaths; 373 cases of tuberculosis, with 167 deaths; 3:1 cases of diphtheria, with 77 deaths; 214 cases of scarlet fever, with 8 deaths; 22 cases of typhoid fever, with 9 deaths; 15 cases of cerebrospinal meningitis, with 20 deaths, and 62 cases of variella; a total of 2,763 cases and 315 deaths.

Hospital Statement Corrected.—At the annual meeting of the trustees of the Hebrew Infant Asylum it was announced that this institution had recorded but one death during the year and that this was probably the lowest mortality for any such institution in the country. It seems that the Colored Orphan Asylum had only one death last year out of an average of 327 children, more than twice the number sheltered by the former institution.

For Quieter City.—The representatives of various women's organizations were on hand at the City Hall on March 1 to endeavor to make an impression on the public health committee of the board of aldermen with reference to the suppression of street noises. Dr. Darlington stated that the health department was frequently called on to suppress noises, and that when a real nuisance was found it was peremptorily suppressed.

Personal.—Dr. Jesse B. Mickle, former superintendent of the Metropolitan Hospital on Blackwell's Island, has resigned on account of failing health.—The two upper floors of Dr. Franklin Shick's home were destroyed by fire, causing damage amounting to \$5,000.—A fire occurred in Dr. Robert Abbe's home on March 1 which did about \$100 damage.—The Rev. John J. Collins has resigned the presidency of Fordham University Medical College in order to take up educational work in Jamaica.

Diphtheria in Hospital.—Dr. I. O. Woolfsh, head of the medical division of Bellevue Hospital, was attacked with diphtheria on March 1, and at once removed to Minturn Hospital. It is alleged that the entire hospital, and especially the children's wards, had a narrow escape from a general infection. The hospital physicians contend that while they held that the cases which caused the disease to spread were diphtheria, the board of health declared them to be only exaggerated cases of tonsillitis.

For Seaside Hospital.—John D. Rockefeller, Jr., has offered to give the Association for the Improvement of the Condition of the Poor \$125,000 toward the erection of a permanent seaside hospital for children suffering from tuberculosis of the bones and glands on condition that a like amount is raised before July 1, and that the permanent maintenance of the hospital is assured. An anonymous donor has promised to give \$25,000 of the fund that must be secured. Jacob H. Schiff, Mortimer L. Schiff and Percy R. Pyne have promised \$5,000 each, and Felix M. Warburg, \$2,000.

Subway Consumption.—Autopsies made at the Bellevue morgue show that some deaths have been due to fine particles of steel in the lungs. This statement was made public after

autopsies made on two subway track walkers within the past month. Dr. Soper, in his report to the rapid transit commission, declared that in samples of subway dust examined by him there occurred more than 60 per cent. of the minute steel particles, and it has been established that the steel dust generated by friction in the subway amounts to a ton a mile each month. Dr. Soper finds the subway cleaner than the streets. General results show that there are twice as many bacteria in the air of the streets as there are in that of the subway. The subway could be made more healthful by substituting a smooth concrete surface for the broken stone ballast between the tracks that forms a nesting place for dirt and germs.

The Smoke Nuisance.—The recent widespread increase of the smoke nuisance has caused a renewal of the agitation for the stricter enforcement of the law governing the escape of smoke and noxious gases within the city limits. The Academy of Medicine has taken the matter up and the president, Dr. Charles L. Dana, has appointed a committee consisting of Drs. Joseph D. Bryant, Robert Abbe and Walter B. James to investigate the matter. Dr. E. M. Crandall, president of the County Medical Society, has also taken up the investigation. On February 23 Dr. Darlington read a paper on "Municipal Regulation of the Smoke Nuisance" before the Society of Chemical Industry, in which he depicted the difficulties of the department in obtaining the conviction of burners of soft coal. Charles T. Barney, who has made an extensive study of this question, says that under a certain section of the charter it is provided that in all judicial proceedings orders of the health department shall at all times be regarded and treated as *prima facie* just and legal, and that whoever shall violate an order of the health department shall be guilty of a misdemeanor and be subject, in addition, to a penalty of \$250, to be recovered in a civil action. It was stated that until September, 1905, the department acted under these sections and obtained prompt compliance with its orders.

PENNSYLVANIA.

Upholding Dr. Dixon.—At the meeting of the Clinton County Medical Society, January 18, resolutions were adopted approving the actions of Dr. Samuel G. Dixon, the state commissioner of health, in enforcing the vaccination laws of Pennsylvania; and unanimously agreeing that the way to prevent smallpox is by vaccination; and that those who try to prevent and bring it into contempt only show their ignorance.

Pennsylvania Relief Report.—The monthly report of the Employed Relief Fund for the Pennsylvania Railroad Company's lines east of Pittsburg and Erie shows that the payments of benefits to its members and the families of deceased members for the month of January amounted to \$143,681.41, of which \$59,081.86 was on account of death, and \$84,599.55 on account of disability by sickness and accident. The payments thus far are stated to have amounted in the aggregate to \$14,484,233.46, of which \$5,958,326.79 were on account of deaths and \$8,525,906.67 on account of disability.

Gifts for Hospitals.—W. L. Schaefer, Pottsville, has given to the Pottsville Hospital \$5,000 to endow a bed for sick and injured children in memory of his deceased wife.—The family of the late J. Preston Thomas, West Whiteland, have given \$6,000 to the Chester County Hospital to endow a room in that institution. By the will of Thomas Wiggins, Berwyn, \$500 was bequeathed to the institution.—Bradlock General Hospital received more than \$4,000 as Christmas offerings.—By the will of the late Martin Bates, Lancaster, \$10,000 is bequeathed to the Lancaster General Hospital.—By the will of the late James B. Oliver \$5,000 is devised to the South Side Hospital, Pittsburg. W. Ellis Corey has contributed \$10,000 toward a hospital for Bradlock.—By the will of John Porterfield, Allegheny, the following institutions are benefited: United Presbyterian Memorial Hospital, \$10,000; Presbyterian Hospital, Allegheny, \$10,000; St. Joseph's Hospital, Allegheny, \$10,000, and on the death of his sister \$100,000 is to be given to the Allegheny General Hospital.

Society Officers Elected. At the regular meeting of the Clearfield County Medical Society, Clearfield, January 11, the following officers were elected for the year: President, Dr. Hiram O. King, Curwensville; vice-president, Dr. John S. Kelso, Woodland; secretary and treasurer, Dr. C. R. McGirk; censor, Dr. Samuel J. Waterworth, Clearfield, and committee on public policy and legislation, Drs. Samuel C. Stewart, Clearfield; J. Frank Rowles and James L. Henderson, Osceola Mills. At the regular quarterly meeting of the Franklin County Medical Society the following officers were elected: President, Dr.

Charles M. McLaughlin, Greencastle; vice-presidents, Drs. John C. Greenawalt, Chambersburg, and William F. Sappington, Webster Mills (Fulton County); secretary, Dr. John J. Coffmann, Scotland; assistant secretary, Dr. H. Clay Devilbiss, Chambersburg; treasurer, Dr. David MacLay, Chambersburg, and censor, Dr. T. H. Weagly, Marion.—At the annual meeting of the Huntingdon County Medical Society, January 11, the following officers were elected: President, Dr. John C. Fleming, Shirlersburg; vice-president, Dr. Charles A. McClain, Mount Union; treasurer, Dr. George G. Harman, Huntingdon; secretary and reporter, Dr. Howard C. Frontz, Huntingdon, and censors, Drs. Rudolph Myers, Huntingdon; Charles Campbell, Petersburg, and Charles R. Bush, Orbisonia.—At the annual meeting of the Lancaster County Medical Society the following officers were elected: President, Dr. Leroy K. Leslie, Barville; vice-presidents, Drs. John P. Roeluck, Lititz, and Samuel H. Heller, Lancaster; secretary, Dr. Park P. Breuneman, Lancaster; treasurer, Dr. George H. Rohrer, Lancaster; reporter, Dr. Park P. Breuneman, Lancaster, and censors, Drs. George W. Berntheil, Columbia; Oliver Roland, Lancaster, and James Mitchell, Lancaster.—At the annual meeting of the Lehigh County Medical Society the following officers were elected: President, Dr. Augustus W. Hendricks, Allentown; vice-presidents, Drs. Palmer J. Kress, Allentown, and Morris F. Cawley, Allentown; recording secretary, Dr. J. Treichler Butz, Allentown; corresponding secretary, Dr. William D. Kline, Allentown; treasurer, Dr. Albert J. Erdmann, Allentown; censors, Drs. H. Herbert Herbst, Allentown; Martin J. Backenstoe, Emaus, and W. B. Erdmann, and reporter, Dr. William A. Hausman, Jr., Allentown.—At the fifty-seventh annual meeting of the Medical Society of Northampton County, held in Easton, January 19, the following officers were elected: President, Dr. Arthur D. Reagan; Easton; vice-presidents, Drs. J. Frank Hahn, Bath, and Harry C. Pohl, Nazareth; secretary and reporter, Dr. J. J. Quincey; corresponding secretary, Dr. John E. Fretz, Easton; treasurer, Dr. Joseph S. Hunt, Easton, and censors, Drs. Charles McIntire, Easton; D. H. Keller and William L. Estes, South Bethlehem.—At the annual meeting of the Perry County Medical Society the following officers were elected: President, Dr. F. A. Gutshall, Blain; vice-presidents, Drs. W. Homer Hoopes, Newport, and Edward E. Moore, New Bloomfield; secretary, Dr. A. Russell Johnston, New Bloomfield; treasurer, Dr. David B. Milliken, Landisburg, and reporter, Dr. Luther M. Shumaker, Elliottsburg.—At the annual meeting of the Warren County Medical Society, January 10, the following officers were elected: President, Dr. William M. Robertson, Warren; vice-presidents, Drs. Otis S. Brown, Warren, and John C. Russell, Warren; treasurer, Dr. Morris S. Guth, Warren; secretary and reporter, Dr. Mary Conant, and censors, Drs. Michael V. Ball, Warren; Christian J. Frantz, Warren, and Charles W. Schmelz, Warren.

Philadelphia.

Hospital Examinations.—The examination for two resident physicians for the Easton Hospital will be held in Easton on Saturday, March 24.

Hospital Report.—A remarkable year's record is shown by the report of the Maternity Hospital. There was but one death in the 72 cases treated during the year, and this was the first death in three years.

Dr. Allen Entertained.—Dr. Richard H. Harte gave a dinner at his residence, March 3, in honor of Dr. Dudley P. Allen of Cleveland, Ohio, secretary of the American Surgical Association. Dr. Allen delivered an address before the Philadelphia Academy of Surgery at the College of Physicians, March 6.

Charitable Bequest.—By the will of the late Louisa Dieterich the Rush Hospital for Consumptives will receive \$10,000 for the maintenance of two free beds, to be called the Daniel P. Dieterich free bed and the Louisa Dieterich free bed. A bequest of \$10,000 is also made for the use of the hospital. After other bequests the balance of the estate, valued at \$54,000, is left in trust for the benefit of the hospital.

Society Officers Elected.—At the annual meeting of the Northern Branch of the Philadelphia County Medical Society the following officers were elected: President, Dr. Howard P. Gelbo; vice-president, Dr. Samuel H. Brown; recording secretary, Dr. R. E. Shrum; treasurer, Dr. John W. Millick; corresponding secretary, Dr. Thomas R. Currie; censor, Dr. Thomas Shiner, and librarian, Dr. Robert J. Hess.

Personal.—Dr. George W. Pfromm has resigned as a member of the assistant medical staff of the Medico-Chirurgical College Hospital. — Dr. Jewellys E. Barker, professor of medicine, Johns Hopkins University, addressed the James

Tyson Medical Society of the University of Pennsylvania on "Personal Observations of the Bubonic Plague in China and the Philippines," February 28.—Mr. G. C. Signor of Tioga County has been appointed superintendent of the Medico-Chirurgical Hospital to take the place of J. E. Ellis. Mr. Signor assumed his duties of director of the institution March 1.

Wistar Institute Honored.—The authorities of the University of Pennsylvania have been notified that the Wistar Institute of Anatomy has been chosen as the central institute for interacademic brain research in the United States. The Imperial Academy of Sciences at Vienna voted the Wistar Institute the best for brain research in this country at a recent meeting and this announcement has just been made. Recently Dr. Henry Donaldson of Chicago, Dr. T. P. Mall of Johns Hopkins Medical School, and Dr. Minot of the Harvard Medical School were elected members of the central commission for interacademic brain research. The work of the brain research at the institute will be under the direction of Dr. Donaldson.

Health Report.—The total number of deaths reported for the week reached 670. This is an increase of 53 over the number reported last week and an increase of 117 over the number reported in the corresponding week of last year. The principal causes of death were: typhoid fever, 43; measles, 16; whooping cough, 10; diphtheria, 9; consumption, 60; cancer, 28; apoplexy, 25; heart disease, 61; acute respiratory disease, 121; enteritis, 27; Bright's disease, 44; appendicitis, 7; suicide, 9; accidents, 33, and marasmus, 6. There were 469 cases of contagious disease reported, with 54 deaths, as compared with 483 cases and 58 deaths for the preceding week. Typhoid fever is still on the increase; 352 cases were reported, with 43 deaths, as compared with 340 cases and 39 deaths in the week previous. There are under treatment at the present in the city about 2,500 persons suffering with typhoid infection.

Widener Memorial for Crippled Children Opened.—The Widener Training School for Crippled Children, with its thirty-five acres of ground attached, was thrown open to the public for inspection, March 3. This is supposed to be the finest institution of its kind in the world. The home has been erected by Peter A. B. Widener as a memorial to his wife, Josephine Widener. It is intended to be a surgical aid to train crippled boys and girls so that they may be able to care for themselves and earn a living. The buildings are of brick and stone, in the colonial style of architecture. The group of buildings is an irregular square of about 400 feet. The main building is 265 feet long, with a depth of 90 feet. In the building are the surgical wards, the kitchen and all the appendages of the culinary department. In one end of the basement is a gymnasium, with dressing rooms and bath rooms. On the second floor are the surgical wards, and on the third floor the operating rooms and laboratory, with rooms for etherization and for use of the surgeons. Lifts and inclined planes will render the transfer of patients from one floor to another easy and painless. The educational buildings will be fitted with machinery and apparatus so that mental and manual training will be carried on together.

Physicians and the Lay Press.—At the meeting of the County Medical Society, February 28, resolutions were ordered to be referred to the directors for further action providing that the society declares that the appearance of articles in the daily press specifically describing the diseases of certain patients and the treatment thereof, together with names of attending physicians, etc., is a violation of Article I, Section 7, Chapter 2, of the Principles of Ethics of the American Medical Association; that the onus of proof of non-responsibility for such publication shall be on those whose names appear in such articles; that if the person so charged fails to convince the censors of non-responsibility they shall cause to appear in two successive issues of the *Weekly Roster* a statement of the facts and a notice that unless the offender shall sign a written agreement to abstain from further similar offense all members of the society shall decline consultation with such offender; and that in case of a second offense the offender shall be liable to expulsion; that the assistant secretary shall keep a scrap-book containing copies of all articles appearing in the daily press relating to regular physicians of Philadelphia, and that this book shall be kept on the secretary's desk for the inspection of members, and that the titles of all articles shall be read at each meeting; that the directors of the society be requested to prepare amendments of the by-laws to accord with these resolutions, and that these resolutions shall appear in every issue of the *Weekly Roster* until and including that for the business meeting of the society in April.

VIRGINIA.

Dr. Chiles Acquitted.—Dr. Luther R. Chiles, Norfolk, indicted for having performed a criminal operation on Miss Atkinson, whose death followed, was acquitted February 19.

Oppose Tax.—The physicians of the state are making another effort to obtain release from the state and local taxes imposed on practitioners of medicine. A committee of which Dr. George Ben Johnston, Richmond, is chairman, is preparing a bill to obtain release from this tax, which will be introduced at this session of the legislature.

Epileptic Hospital Bill Passes.—The senate has passed a bill creating a state epileptic hospital on the site given for that purpose by the late S. R. Murkland on the Anheuser Palisades, opposite Lynchburg. The colony will be a branch of the Western State Hospital, Staunton, and the state will provide for its maintenance by increasing the appropriation for that institution.

Personal.—Dr. Walter A. Plecker, Hampton, has been elected health officer of Elizabeth City County to succeed Dr. John W. Brown, resigned.—Physicians of Lynchburg presented Dr. Abram I. Clark of that city with a silver loving-cup as a token of esteem, from the Academy of Medicine on January 20, the eighty-ninth birthday anniversary of Dr. Clark.—Dr. Charles R. Grandy, Norfolk, has been appointed a member of the State Board of Health, vice Dr. Vernon G. Culpepper, Portsmouth, deceased.—Dr. Chertsey Hopkins, assistant physician at the Western State Hospital, Staunton, has resigned.—Dr. William F. Drewry, who some time ago was elected superintendent of the Western State Hospital, has decided not to accept the position, but to remain where he has been for a number of years, superintendent of Central State Hospital.—Dr. George S. Walker, who has been assistant superintendent of the Western State Hospital for the past twenty years, has resigned.—Dr. J. S. De Jarnette was elected superintendent to succeed the late Dr. Benjamin Blockford.—Governor Swanson has appointed Dr. Frank S. Hope, Portsmouth, quarantine officer for the district of Elizabeth River to succeed Dr. Julian Norfleet.

GENERAL.

Change Date of Western Surgical.—The Western Surgical and Gynecological Association will meet in Salt Lake City, Aug. 31 and Sept. 1, 1906. The change from the usual Christmas time for the meeting is in accordance with a general vote just taken. Dr. A. T. Mann, Pillsbury building, Minneapolis, is secretary-treasurer.

Monument to Mikulicz.—An international committee has been formed to solicit and receive contributions for a monument in honor of the late distinguished surgeon, Johannes von Mikulicz-Radecki, of Breslau, Germany. Those who wish to express in this way their esteem and affection for Professor von Mikulicz, their appreciation of Germany's splendid achievements in surgery and their desire to strengthen the cordial relations existing between the men of science of the two countries, may send contributions to any of the following: Drs. W. W. Keen, 1729 Chestnut Street, Philadelphia; W. S. Halsted, 1201 Entaw Place, Baltimore; J. B. Murphy, 100 State Street, Chicago; F. Kammerer, 51 East Sixty-sixth Street, New York.

International Medical Congress.—The arrangements of the American national committee have now been fully made. Those who have planned to present papers at the congress should at once send short abstracts of their papers to the secretary-general, Dr. Miguel Bombarda, Madrid, Spain. The official delegates from this country have been appointed by the secretary of state as follows: Drs. L. S. McMurtry, Louisville; John H. Musser, Philadelphia; Frank Billings, Chicago; W. W. Keen, Philadelphia; Nicholas Senn, Chicago; F. A. Shattuck, Boston; R. Matas, New Orleans; Albert Vander Veer, Albany; Walter Chase, Boston; E. DeVitt Connell, Portland, Ore.; and Ramon Gutierrez, New York City. At the congress an orator will represent each country by delivering an oration before the assembled sections of the meeting. Dr. Nicholas Senn will represent the United States and will deliver an oration on "The International Study of Carcinoma." Further information respecting the congress may be found in THE JOURNAL, Feb. 17, 1906, page 521, and Jan. 20, 1906, page 207.

CANADA.

Health of Toronto.—Toronto was a healthy city in February. The number of cases of diphtheria in February was 59, as against 96 in January and 111 in February, 1905. There were 9 cases of scarlet fever and 15 of typhoid fever.

Compulsory Vaccination in Toronto.—The board of education of the city of Toronto passed a resolution doing away with the compulsory vaccination of school children. Dr. Ogden, one of the oldest members of the board, refrained from voting, favoring sending the question to the health officer for his opinion.

Society Elects Officers.—The annual meeting of the council of the College of Physicians and Surgeons, New Brunswick, was held at Fredericton, February 9, when the following officers were elected for the ensuing year: President, Dr. J. P. McInerney; treasurer, Dr. Thomas Walker St. John; registrar, Dr. Stewart Skinner.

Ontario Health Report for January.—During January the total number of deaths from all causes was 2,477. There were 141 cases of smallpox, with no deaths, and 168 cases of typhoid fever, with 51 deaths. Fort William, at the head of Lake Superior, had 106 of these cases, with 13 deaths. There were 165 deaths from consumption.

Ontario Nurses to Organize.—The nurses of Ontario have before the legislature a bill by which they seek incorporation as the "Graduate Nurses' Association of Ontario." The government is to be vested in a council of fifteen, four of whom are medical men. Power also is asked to prescribe courses of study, to conduct examinations and to issue diplomas.

Personal.—Dr. J. W. Stirling, Montreal, has been appointed to the chair of ophthalmology at McGill University, to succeed the late Dr. Frank Buller. Dr. Stirling was born at Halifax in 1859 and received his degree from the University of Edinburgh in 1884.—Dr. A. B. Macdunnell, professor of physiology in the University of Toronto, has been appointed a fellow of the Royal Society of England.—At the annual convocation at Queen's University, Kingston, on April 12, the degree of doctor of laws will be conferred on Dr. C. K. Clarke, superintendent of the Toronto Provincial Hospital for the Insane.

Hospital News.—The Charles Alexander Memorial Fund in aid of the Montreal General Hospital now amounts to \$200,112. Fifty thousand dollars are needed to complete the memorial. Dr. G. H. Mathewson has been appointed oculist to the hospital to succeed Dr. J. W. Stirling.—The Alexandra Contagious Diseases Hospital, Montreal, is now rapidly nearing completion. The institution will be managed by a medical board, composed of three members, one from the General Hospital, one from the Royal Victoria Hospital and one from the Western Hospital. Dr. J. C. Fyche, a graduate of McGill, will be superintendent, and he is now in training under Dr. McCallum, of the Boston City Hospital.—Dr. R. W. Bruce Smith, inspector of public institutions in Ontario, recommends that an asylum be located in Ontario north of Lake Superior. He also recommends special treatment for chronic inebriates. During 1905 there were 11,000 convictions in Ontario, with a population of 2,000,000.—According to the thirty-eighth annual report on the lunatic and idiot asylums of Ontario there were 6,213 patients certified insane on Sept. 30, 1905, an increase of 632 for the year, during which 1,130 patients were admitted.

FOREIGN.

Unveiling of Bust of Liebault.—A bust of A. A. Liebault, the founder of the "Nancy school," has been installed in the School of Psychology at Paris and was unveiled with much ceremony, February 1. Prominent psychologists were present from various countries and numerous telegrams were received from others unable to be present. Eighty persons partook of the banquet. Liebault was born in 1823 and died in 1904. His efforts to introduce scientific hypnotism into therapeutics dated from early in the sixties.

War on Consumption in the Home.—The management of the Brompton Hospital for Consumption—London's great hospital for the treatment of this disease—is about to initiate an important departure in its treatment of tuberculosis. A joint subcommittee has been appointed, under the advice of the medical staff, to consider the feasibility of reaching the source of infection in the homes of the patients. Dr. Newsholme, the medical officer of health for Brighton, will co-operate and it is hoped that every member of a consumptive's family may be brought under the direct care of the hospital staff.

Prizes for Designs for Village Baths.—The German Public Bath Society has offered prizes of \$150 and \$100 for the best design for public baths for small towns and villages. The competition is designed to arouse interest in the subject of public baths in small places, bathing in rivers and ponds not being considered enough for the hygiene of the inhabitants all the year around. The jury to pass judgment on the designs consists of prominent physicians, architects and others. The designs must be sent in at once to the office of the society, Berlin NW. 6, Karlstrasse 19, addressed to the *Deutsche Gesellschaft f. Volkshäuser*.

Pure Food Regulations in Madrid. The *Siglo Medico* gives the details of decrees recently promulgated by the alcaide of Madrid which are in accordance with the most advanced ideas in regard to the necessity for arresting the adulteration of food and other antihygienic evils. One clause enforces the screening of food away from flies, another forbids the use of impure water in cooking and washing dishes. A fine of from 5 to 50 pesetas (\$2.50 to \$25) is to be imposed for infraction of the rules. Our exchange comments that the decrees would be worthy of the highest encomiums if only they were meant to be enforced. Experience has shown that they will never get beyond the pages of the official records on which they make such a fine showing.

Increase in Liverpool of Drunkenness Among Women. The statistics of the chief constable of Liverpool show that of 7,700 charges of drunkenness more than one-third were against women. At the recent annual meeting of the Liverpool Society for the Prevention of Cruelty to Children it was stated that the society last year dealt with 10,288 children, and that the chief cause of the misery, cruelty and neglect was drunkenness, especially on the part of the mothers, and that while drunkenness among men is actually decreasing, among women it is greatly on the increase. The Liverpool licensing bench has resolved that the police should be instructed to report houses where female drinking is excessive, so that the bench may deal with them under the compensation clause of the licensing act.

Silver Jubilee of Berlin Internal Medicine Society. On February 19 the Berlin *German für innere Medizin* celebrated the twenty-fifth anniversary of its foundation. It was organized in 1881 mainly by the efforts of Ernest von Leyden, and is now one of the largest associations of the kind in Germany. Its transactions contain many notable communications, and its success in conducting collective inquiries on various scientific themes attracted wide attention, especially its great collective inquiry on influenza. The festival address was delivered by A. Fraenkel on "Modes of Dissemination of Pulmonary Tuberculosis from the Clinical Standpoint." A number of honorary and corresponding members were elected, among the former Quinke of Kiel, von Schrötter of Vienna, Maragliano of Genoa, Pel of Amsterdam and Kernig of St. Petersburg. The jubilee banquet was held a day or two later.

No Benefits from Compulsory Disinfection at Paris.—The *Semaine Méd.*, for February 14 cites statistics showing the number of cases of various communicable diseases in Paris during the last decade. Notwithstanding the regulations for compulsory disinfection, the number of cases of diphtheria and of scarlet fever was as large in 1904 as in 1895 (respectively 4,227 and 3,279 in 1895 and 4,653 and 3,592 in 1903). The number of cases of smallpox increased from 542 in 1895 to 822 in 1904, and of typhoid fever from 1,389 to 2,635. The editorial states that statistics from other cities show a similar lack of any decline in the number of cases of communicable diseases since the enforcement of compulsory disinfection. The number of cases keeps about on the same level or is higher than before these measures were introduced. The editorial regards this as an argument against extending compulsory disinfection to tuberculosis as some are advocating.

Annual Meeting of the Medical Society of Victoria, Australia. The annual meeting of this society was held in January. In his presidential address, Dr. A. Jeffreys Wood, Melbourne, reviewed at length the history of the society from the time it was organized to the present. He referred to the two methods whereby the medical profession of Australia might be effectively organized: The first suggestion is that a new association be created on the lines of the American Medical Association and called the Australasian Medical Association; the other is that all the medical societies throughout the commonwealth should become branches of the British Medical Association. Dr. Wood said that the necessity for organization in the profession is daily becoming more apparent. "The days are past when a medical man can stand aside from medical politics and pursue the even tenor of his way without detriment to himself or to his colleagues." He concluded his address by urging the benefits to be derived from affiliation with the British Medical Association.

Prize for Professor Bier. The medical faculty of Heidelberg has awarded the Kussmaul prize to the professor of surgery at Bonn, August Bier, for his studies on artificially induced congestive hyperemia as a therapeutic measure. Bier is only 45 years old, but he has been preaching for years the advantages of measures to induce active or passive hyperemia in the treatment of various affections. His views were received with in-

difference at first, but have gradually gained more and more adherents until now they have become firmly established in current surgical and medical practice. Some go so far as to call this work the greatest achievement in surgery since the introduction of antiseptics. His latest application of the method of congestive hyperemia by interrupted circulation as a means of treating acute inflammations was regarded with amazement at first, but more and more testimony is constantly accumulating in its favor. All agree in the remarkable subsidence of the pain after the circulation has been interrupted by the tourniquet above the lesion. The Kussmaul prize was endowed not long ago by Czerny as a memorial to his father-in-law, Prof. Adolph Kussmaul. This is the first time it has been awarded. Bier's method of passive congestion is discussed editorially on page 726.

Organization of the Profession in Austria.—The physicians in lower Austria who have charge of the free vaccinations have protested for years against the remuneration allowed them by the state for this and similar official medical work. The veterinary surgeons receive 20 cents for each animal vaccinated against hog cholera, but the rate for vaccinating a human being is only 20 hellers, about equal to 5 cents. The fees allowed for other medical duties are proportionately small, and the physicians are now banding together to demand juster remuneration from the authorities. They say that they are "paid less for a careful medical examination of a lousy tramp than the barber gets for cutting the vagrant's hair." The spirit of organization is spreading and the medical societies are standing by their colleagues in the opening strife. The physicians are opposing what they call "passive resistance" to the authorities, reporting every case in which there is a suspicion of infectious disease as "suspicious of scarlet fever," or "of diphtheria" or "smallpox." More than 10,000 cases had this been reported as "suspicious" during the first week, overwhelming the district health officers whose duty it is to examine each suspicious case. Hitherto they have been notified only when the practitioner was measurably sure of a definite diagnosis.

Recent Decisions of the German Medical Court of Honor.—The three latest decisions deal with questions affecting the organized action of the members of the profession in respect to contract practice. One physician was fined by the local court of honor because he had accepted a position with the local sickness insurance society at a 3-mark rate when all the medical officers of the society (Krankenkasse) had resigned in a body because the society had refused to increase their remuneration to a 3.5-mark rate. Appeal to the supreme court of honor resulted in the acquittal of the physician, as it was held that his acceptance of a position with the society after the medical officers had all resigned did not bring him within the jurisdiction of the court of honor, especially as the rate accepted was not ignominiously low. In another case a physician accepted a position with the sickness insurance society when the members of the local medical chamber had voted that none of its members should accept such a position until the company agreed to certain conditions. The physician was condemned for this conduct by the court of honor, but as the local medical chamber was very loosely organized and as he had not been informed in regard to the result of its deliberations he was dismissed with merely censure. In another case eleven physicians voted in the minority in their local medical chamber (Arztelkammer) against certain conditions to be demanded of the insurance company ("free choice by the patient of his physician"). Being outvoted, they withdrew from the medical chamber and accepted the company's terms. The court of honor dismissed the suit against them.

LONDON LETTER.

The Problem of Milk Supply.

Dr. A. C. Houston has presented an important report on his bacteriologic examination of milk to the London County Council. It has been computed that in the United Kingdom in 1901 there were 4,102,000 milk cows and that the total yield of milk per annum was 1,722,840,000 gallons. It has been suggested that 20 per cent. of the milk cows are tuberculous and that 2 per cent. suffer from tuberculosis of the udder. Under existing conditions the opportunities of milk becoming contaminated both during and after milking are numerous. The cow may be coated with filth; the milk may be dirty; the milk utensils may be unclean and the air of the byre may be loaded with excrementally polluted dust. There are fresh opportunities for the ingress of filth during the transit of the milk and on the premises of the dairy shops and milk purveyors. Dr. Houston observes that bacteriologic testings can do little more than show whether such remedial measures as may from time to time be suggested or demanded have been taken. The actual

disease-producing power of milk can not be measured by the bacteriologist. He can hardly even say, unless bacteria are almost absent, that a particular sample of milk is devoid of power to cause disease. He can measure the amount of filth in milk, however, and determine its biologic qualities. Bacteriologic tests and standards are not, strictly speaking, preventive measures, but as they may be the means of forcing milk dealers to carry out suggested reforms they are indirectly remedial measures. Dr. Houston suggests the enforcement of the following conditions: Cows should be kept clean and housed in well-ventilated, clean byres. The milkster should be cleanly in his person and in his methods of procedure. The first milk should be rejected. All milk utensils should be kept scrupulously clean. The milk should be strained through a clean strainer. The conditions under which milk churns are conveyed from place to place and milk is carried to the consumers' premises should be greatly improved. Dairy and milk purveyors' shops should be kept clean. All persons engaged in handling milk should pay special regard to the importance of personal cleanliness. Far greater precautions than exist should be taken to exclude dust, flies, etc. The water used for washing dairy utensils should be potable water. On the question of personal cleanliness Dr. Houston says that no person who has contracted typhoid fever is fit to handle milk, even if long convalescent, in the absence of medical supervision. The danger of typhoid bacilluria must not be forgotten. Recently an epidemic of scarlet fever was traced to a man in the late stages of an attack of that disease who was employed to milk cows.

The Prevention of Consumption.

Sir William Broadbent has addressed an important memorial to the Metropolitan Asylums Board on the prevention of consumption. He points out that the International Congress on Tuberculosis held in Paris brought into prominence the importance of the prevention of consumption from a social point of view. He urges the board (which now controls all the fever hospitals of the metropolis), to constitute itself the tuberculosis authority. The first step would then be to ascertain the number and distribution of the cases of consumption in the metropolis, and the stage of the disease, with the circumstances and surroundings of the sufferer. This would be effected by a system of notification. The notification would be followed in the case of the poor by the visit first, it is hoped, of some member of a woman's association, such as in Manchester has been found to remove all objections on the part of the families; next, of a sanitary inspector, who would carry out the necessary disinfection. Thus advanced cases, from which the dissemination of the disease mostly takes place, would be identified and surrounded by protective and preventive measures. The destruction of the sputum would be secured, the importance of open bedroom windows would be inculcated and the removal of dust by damp cloths instead of dusting and sweeping would be taught. In a large proportion of the cases these measures would be sufficient to diminish the dangers of dissemination so that the patient might be treated at home. He would be surrounded with more comfort and would have a better chance of recovery. The periodical visits of women visitors and inspectors would insure the carrying out of the precautions. In advanced cases the patients should be removed to some home, thus removing a source of disease and diminishing the privations of the family, conducive to disease. No expenditures on buildings would be required if some of the hospitals provided for smallpox or other fevers, now unoccupied, are made available. In an important paper read before the Paris congress, Dr. Newsholme, health officer of Brighton, showed that the greater diminution in the death rate from consumption in this country as compared with Ireland and France, and with Germany before the establishment of numerous sanatoria in that country, has been due not merely to improved social conditions, but largely to the reception of advanced cases into the infirmaries and their removal as centers of infection.

Cremation in Great Britain.

In the past year there has been no marked progress in the use of cremation as a means of disposing of the dead. The total number of cremations was 600, as against 566 in 1904 and 475 in 1903. In the erection of crematories, however, distinct progress has been made; in 1904 there were only nine, while in 1905 there were twelve. The total number of cremations performed in Great Britain since the first crematorium was established at Woking in 1885 is 5,018. During 1905 crematories have been opened at Leeds and Bradford. A third is in process of construction at Sheffield. Thus though the progress of cremation is slow in regard to numbers, the area of operation is gradually extending.

Pharmacology

A Phosphorized Cerebro-Spinant.

FALL RIVER, MASS., Feb. 22, 1906.

To the Editor:—Among the proprietary medicines offered to physicians is one called Freligh's Tonic and bearing the striking sub-title of "A Phosphorized Cerebro-Spinant," the formula of which is: Cinchona, nux, ignatia, matricaria, free phosphorus, C. P. No quantities whatever are given, but its indications are "paralysis, vertigo, epilepsy, Bright's disease (early stages), neurasthenia, debility, debilitating losses, mental failure, spinal weakness, nervous dyspepsia, all troubles affecting the brain, nerve centers and spinal cord, and as a safe and powerful aphrodisiac."

The literature which accompanies it is very striking, and if the firm who get it up are no more familiar with the action of drugs than they are with the meaning of the words which they use to describe its action, I think the profession at large had better make their own combinations of these remedies rather than trust to one which is offered to them at the price of \$1 per ounce. After describing how the remedy is combined in such a way that a dose of from 5 to 10 drops in half a glass of water is all that is needed to produce the desired effect and secure beneficial results at once, the descriptive circular says:

"Those familiar with the action of drugs know the homogeneous relations they bear to each other, how their pathogenetic and curative spheres are enlarged and dynamitized by a judicious combination, extending their spheres of usefulness, and governing numerous indications. For such, but a short acquaintance with the Tonic is necessary to convince them that its remedial power and scope far exceed those of any or all the remedies it contains, when used singly."

"A very causal reference to the pathogenetic and curative action of the Tonic will show how completely all of these symptoms and diseases come within the preventive and its curative sphere, together with that voluminous class connected with indigestion and a want of proper assimilation."

It strikes me that the words "pathogenetic" and "curative" hardly go together in the same sentence, descriptive of the same remedy, unless one is considering both the poisonous and the therapeutic action of a drug, and then the dose would necessarily be different. I personally have no use for any tonic which is pathogenetic, and I hope no member of the profession has.

Further on in the same circular, under the heading of "Dyspepsia," it states that "the formula of the tonic shows how the pathogenetic and curative action of its several constituents meets the exigencies of any phase of indigestion." I take it that the pathogenetic action of the tonic is so great that the disease which it produces causes its owner so much trouble that he forgets entirely the dyspepsia, and so in this way the dyspepsia is cured. It seems to be possible with this remedy to cure all cases of indigestion, functional disorders of the brain, threatened softening, progressive locomotor ataxia and general paralysis, but it is still more brilliant in those cases developed by the advancement of age. For these conditions it comes nearer being the fountain of youth for which Ponce de Leon sought two or three centuries ago than anything which has yet been brought to the attention of the human mind.

The circular closes with the statement:

"The wide range of the curative sphere of this article is truly remarkable. For while it is not a catholon, nor is it pretended to be, it covers more symptoms and is curative to more diseases of an alarming character than any other one remedy or combination of remedies, within the limits of our materia medica, or books of medicinal formulae."

It is stated at the beginning of the circular that this is sent solely to the profession, so it must be assumed that the profession is using this remarkable medicine. With two or three such medicines in his grip, a physician should be entirely independent of the Pharmacopœia, the National Formulary and all the old standbys.

GEORGE L. RICHARDS.

A Letter, a Reply, and Comments.

[THE LETTER.]

JOSEPH McDONALD, JR., M.D.

EAST ORANGE, N. J., Feb. 16, 1906.

Dr. J. A. Pettit, Portland, Ore.

Dear Dr. Pettit:—I have read your article in the last issue [Feb. 17] of THE JOURNAL A. M. A. on "The Evils of Proprietary Medicine," and I can not refrain from expressing to you my sentiments.

This tirade against nostrums and proprietaries is, in my estimation, insulting to the medical profession. The doctors of America are as a body an intelligent class and quite able to decide which is and which is not a suitable remedy to be administered to their patients. It must be left to the individual opinion of the physician prescribing whether the product is or is not a nostrum, for this reason that what might appeal to one as a legitimate proprietary article, to another would seem a rank nostrum.

Now eliminating every proprietary or so-called proprietary remedy from our list of useful remedies, would mean that we must give up those remedies manufactured by legitimate houses, these same products conforming to the prescribed rules in the Pharmacopœia, the same should be compounded by the druggists. You must not forget, doctor, that the large manufacturing chemists make it an aim to purchase the best crude drugs that the market produces, while the druggist is supplied by his wholesaler to whom he is many times subsidized. As a consequence cheap and inert drugs are furnished and compounded. Inasmuch as you have committed yourself on the proprietary question, I would suggest that you take a broader view of the situation. From your article I should say that you read only THE JOURNAL of the A. M. A., as you refer in your comments to the advertisement of Kutnow's powder and their method of introducing their goods in Europe as well as to rehash attacks made on other manufacturers.

If you had been well posted on this situation you would have known (I refer now to Kutnow) that other manufacturing chemists are doing identically the same thing, and these chemists are considered ethical from the standpoint of THE JOURNAL of the A. M. A.

I would call your especial attention in this respect to Angier's Petroleum Emulsion, which advertises most extensively to the public in Europe and I believe carried an advertisement in the same publication from which the advertisement of Kutnow's Powder was reproduced.

I take the liberty of enclosing herewith a few pages of a little magazine [1] that occasionally comes to my office, showing that Angier's Emulsion, which carries an advertisement in THE JOURNAL A. M. A., and is considered ethical, nevertheless advertises to the laity in Europe.

My letter to you, doctor, is not in defense of Kutnow's Powder or any other article or product. It is merely a suggestion that you view the situation from a non-biased standpoint and also consider that the profession of America as a body are intelligent men, and you are more liable than otherwise to offend the doctor by preaching to him of his presumed incompetency than you are to convert him to your way of thinking.

J. McDONALD, JR.

[THE REPLY.]

PORTLAND, ORE., Feb. 28, 1906.

Dr. Joseph McDonald, Jr., East Orange, N. J.

Dear Sir:—I am in receipt of your letter of the 16th inst. in criticism of my article in THE JOURNAL A. M. A. of February 10, terming it a tirade, etc., against nostrums and proprietary preparations (which you seem to uphold as benefactors of a medical profession) and an insult to the medical profession.

In reply, I would beg to directly contradict your nomenclature. That which you term a "tirade" is simply a plain statement of plain facts, and that which you term an insult to the medical profession is regarded by all the medical profession who have talked with me or written me, in the words of the countryman, "them's my sentiments." To understand the motives which actuate your adverse criticism, I would have first to know that of which I am now ignorant, viz.,

your possible professional and commercial alliances and interests [2]. If you have any heart or money interests in products sold to our profession, a discussion of the merits of this matter would be futile, because by reason of those circumstances you would not be open to conviction. I certainly should not try to convert to a gold standard an advocate of silver currency who is possibly interested in silver mines.

I have read the magazine from which you enclose clippings. If there is a biased and one-sided magazine in this country, you can find it under that title. You accuse me of confining my reading to THE JOURNAL A. M. A.; and I believe I may justly accuse you of confining your reading matter to the small sheets of this narrow-minded paper you enclose to me; and I think that all will agree that my choice of reading matter is a far better selection than yours. The journals which come to my desk are carefully selected for their scientific character and not for their commercial prominence.

You conclude by saying you are not defending Kutnow's Powder or any other article, but the general construction of your letter influences me to state in reply that I can not help feeling you are defending "something." I will not try to convert you, doctor, because I am afraid I can't.

J. A. PETTIT.

[THE COMMENTS.]

[1. The "little magazine" referred to is the *American Medical Journalist*, November, 1905, issue. This publication is owned or managed by Mr. D. A. O'Gorman. Mr. D. A. O'Gorman owns or manages the O'Gorman Agency. The O'Gorman Agency handles the advertising accounts of the Lawrence (*Medical Brief*) interests. At least a good part of the following preparations are numbered among them: Echthol, Bromidia, Neurilla, Sanmetto, Cactina, Seng, Chionia, Peacock's Bromides, Celerina, Iodia, Papine, Pil Hemorrhoidia, etc. The "little magazine" seems to be the official organ of those interests that are not in accord with the present movement against nostrums by the American Medical Association. The advertisement of Angier's Emulsion was refused further space in THE JOURNAL for reasons that it is not necessary to give in this connection, and ceased to appear after Nov. 4, 1905, issue. It is interesting to note that while the *American Medical Journalist* for November, 1905, directed attention to the fact that this preparation was being advertised to the laity abroad, this particular issue was not published until February, 1906—three months after the advertisement ceased to appear in the advertising pages of THE JOURNAL.—Ed.]

[2. Joseph McDonald, Jr., M.D., graduated from the Baltimore University School of Medicine in 1904. To the best of our knowledge he has never practiced medicine. Previous to April, 1905, he was manager of the *International Journal of Surgery*. Since that date he has purchased the *American Journal of Surgery* (formerly the *American Journal of Surgery and Gynecology*, owned and edited by Dr. Emory Lanphear), of which he is at present the managing editor and owner or part owner. A casual glance through the advertising pages of the *American Journal of Surgery* will readily indicate where Dr. McDonald's vested interests lie.—Ed.]

Formula of Ayer's Cherry Pectoral.

LOWELL, MASS., Feb. 19, 1906.

To the Editor:—On page 446 of THE JOURNAL, February 10, is a note from Dr. Frank L. Smith, of Stafford Springs, Conn., which is likely to call discredit on this house, and yet which we are confident Dr. Smith would never have written had he been acquainted with the facts in the case.

For about sixty years Ayer's Cherry Pectoral was made according to the original formula of Dr. J. C. Ayer, which is here correctly given by Dr. Smith. But about one year ago we decided to publish the formulae of our medicines, hence we took advantage of this fact to change these formulae. The formula we adopted for Ayer's Cherry Pectoral was that recently given in THE JOURNAL. The old preparation was called Ayer's Cherry Pectoral. The new preparation is known as Ayer's Cherry Pectoral (Revised Formula). The formula of the old preparation was never printed on the label. Every bottle of Ayer's

Cherry Pectoral that has left this establishment for nearly a year has had the new formula printed as a part of the label.

Therefore it is true that there are two kinds of Ayer's Cherry Pectoral on the market: the old kind formula, of which Dr. Smith gives on page 446, and the new kind, containing the terpin hydrate and heroin, as recently given in *THE JOURNAL*. We presume it will be many years before all of the old Cherry Pectoral will be entirely off the market.

CHARLES H. STOWELL, M.D.,

Treasurer and General Manager, J. C. Ayer Company.

Proposed Canadian Legislation on Patent Medicines Indorsed.

The Vancouver Medical Association met February 13 and indorsed the bill now before the legislature of British Columbia for the regulation of the sale of patent medicines. The society will also ask the medical council to notify the physicians of the province regarding proprietary medicines said to be equally fraudulent. The department on island revenue at Ottawa has issued a bulletin regarding the analysis of certain patent medicines at present on the Canadian market.

Medical Legislation

The Opportunity for the Pure Food Bill.

The Pure Food Bill is now in the House of Representatives, having passed the Senate. It, therefore, stands a good chance of becoming a law, provided sufficient interest is taken by the public and by the profession to offset that brought to bear by the organizations that are opposing the measure, for all that these organizations can now do is simply to influence congressmen through public opinion. Their arguments are worn threadbare; money will not count. Consequently, their only method will be to influence congressmen through individuals, such as the druggists, who are appealed to by the "patent-medicine" men in the following letter. There is a clause in the bill, as passed by the Senate, to regulate "patent medicines," but it practically amounts to a joke. We understand, however, that the joke has been taken in dead earnest by the committee to which the bill was referred in the house, and will be modified so as to be effective for some good in preventing fraud in proprietary medicines. This is what is referred to in the following letter, written by the chairman of the committee on legislation of the Proprietary Association of America and cautiously sent where it is expected to do good. This letter shows that the "patent-medicine" men realize what is going on and are acting accordingly. We do hope that every reader of *THE JOURNAL* will do his best and take the hint from the Proprietary Association and write to his congressman to support the Hepburn bill. While there is no particular hurry about doing this now, it is well to bear the matter in mind and act as soon as the committee reports the measure.

THE PROPRIETARY ASSOCIATION OF AMERICA.

COMMITTEE ON LEGISLATION.

CHICAGO, March 1, 1906.

Gentlemen:—The situation at Washington has taken a decided turn and Mr. Douglass, who is there, wires that the situation is serious, and that there is a possibility that a provision for the publication of the formula on proprietary medicines for interstate commerce will be added to the Pure Food Bill by the House committee.

Mr. Douglass wires also that the *Ladies' Home Journal* Bill may be introduced in the House, for the District of Columbia, and that it is indorsed by the district officials on recommendation of the health officer.

Every influence you can bring to bear on your congressman should be brought at once. There should be no let up to your endeavor until the Pure Food and the District of Columbia bills are disposed of satisfactorily. You will readily realize the importance of prompt action.

Take these matters up with your congressman by wire, and have every druggist possible wire his congressman to oppose the passage of formula legislation, either for the District of Columbia, or as an amendment to the Pure Food Bill.

We will endeavor to keep you posted regarding developments and suggest that you keep in touch, from your end, with this office. It is important that telegrams be sent to members of congress by druggists and others interested. Yours very truly,

JOHN W. KENNEDY, Chairman.

Address—Room 1107, No. 184 La Salle Street.

The Vote on the Pure Food and Drug Bill.

The American Medical Association has been active in its support of the Hepburn pure food and drug bill which passed the United States Senate February 21. The agitation in behalf of this measure has had no more influential support than that which was derived from the petitions sent from practically every county in the United States, signed very generally by the medical profession of each county, urgently requesting senators and members of the House of Representatives to support the measure.

Now that it has passed the senate by a splendid vote of 63 to 4, it devolves on every medical man in the United States—particularly on every one who has signed a petition or sent a letter to Congress in this behalf—to write each senator who voted for the measure and thank him for his attitude on this question.

It is only by expressed appreciation of favors asked for that other favors may be secured in the future. The vote was as follows:

YEAS—63.

Alger.	Depew.	Hepburn.	Overman.
Allee.	Dick.	Kittredge.	Patterson.
Ankeny.	Dillingham.	Knox.	Penrose.
Beveridge.	Dolliver.	La Follette.	Perkins.

Help the Pure Food Bill to Pass.

ATLANTA, NEB., March 5, 1906.

To the Editor:—In my capacity as chairman of the committee on pure foods and pure drugs of the National Legislative Council of the American Medical Association I appeal to the members of this council, resident in the different states of the country, to lose no time in urging on the county medical societies with whom their members of the house of representatives live, to send at once to each one of them resolutions, both strong and unequivocal, demanding respectful attention to the wishes of their constituents for the passage of the Hepburn bill, with the amendments of the senate non-concurred in, or for the passage of the Hepburn bill, which is identical with the Hepburn bill in spirit before the amendments were attached to it by the senate. Urge on the representatives that this measure has become a crying need and that the people intensely feel it, especially when they ask so little in the bills, namely: "Label correctly what you put up and leave to us, the people, the choice of buying your products!"

I trust the members of my committee, as well as the members of the council from the different states, will pardon me and *THE JOURNAL* if any or all of the county societies should act at once on this appeal, even if they do not first receive their invitation to do so. Time is short and every word of warning not to go to sleep, urged by *THE JOURNAL*, is only too appropriate, in the face of the activities displayed by those who, for the sake of gain, care very little whom they injure or what they destroy. Nebraska has already commenced to apprise its congressmen of its wishes. These men are wide awake and know

that their people are in dead earnest in this matter; in fact, they themselves feel the need of this legislation for their own families; they will need little urging, and I sincerely believe this will prove true of an overwhelming majority of the members of the house of representatives.

A. S. v. MANSELD.

New Jersey Ready to Work.

Dr. L. M. Halsey, Williamstown, N. J., member of the National Legislative Committee for New Jersey, has completed the organization of the National Auxiliary Legislative Committee for that state. Dr. Halsey called for a meeting of the Committee on Legislation of the State of New Jersey at Trenton, March 6, to take action on the anti-nostrum bill now pending in their state legislature, based on the act published in the February number of the *Ladies' Home Journal*.

Association News

Headquarters for Section on Practice of Medicine.

We are asked to announce that the Hotel Somerset has been selected as the headquarters for the Section on Practice of Medicine for the Boston session. It is suggested that there will be a better chance for acquaintanceship if as many members of the section as find it convenient to do so will register at that hotel.

NEW MEMBERS.

List of new members of the American Medical Association for the month of February, 1906:

ALABAMA.

Alexander, J. F., Blocton.
Black, O. E., Wilsonville.
Brown, J. T., Riverside.
Bridgman, F. E., Huntsville.
Burns, R. A., Alabama City.
Burshaw, L. R., Headland.
Boggs, J. W., Woodville.
Brown, J. M., Gadsden.
Blue, J. H., Montgomery.
Crutcher, J. S., Athens.
Lawrence, T. P., Gadsden.
Duff, W. S., Ft. Payne.
Duckett, L. F., Florence.
Fancett, G. L., Gadsden.
Hacood, M. H., Mt. Willing.
Hall, B. M., Huntsville.
Harris, E. A., Coal City.
Henry, T. H., Tusculum.
Hagan, W. J., Athens.
Lee, E. F., Consul.
Laney, M. W., Eden.
Moore, J. C., Anniston.
Naples, W. C., Anniston.
Nathan, C. S., Talladega.
Palmer, C. R., Tusculum.
Robinson, T. P., Bessemer.
Sommes, R. O., Camden.
Simms, B. B., Talladega.
Stringer, W. L., Falkville.
Woodson, J. L., Coal Valley.
Warwick, B. B., Talladega.
Williamson, E. O., Gurley.
White, W. Y., Anniston.

ALIZONA.

Levensgood, H. W., Helvetia.

ARKANSAS.

Blackwell, O. G., Pine Bluff.
Blackburn, E. W., Ozark.
Blakemore, J. E., Van Buren.
Campbell, J. M., Russellville.
Ellsworth, E. J., Hot Springs.
Foster, J. H., Ft. Smith.
Houston, A. L., Clarendon.
Harris, A. E., Little Rock.
Jones, Ernest, Commercial.
John, J. W., Pine Bluff.
Lucas, O. K., Little Rock.
Linds, Giles, Van Buren.
Presley, W. L., Morrilton.
Thorne, F. L., Little Rock.
Vaughan, M., Little Rock.

CALIFORNIA.

Barton, H. P., Los Angeles.
Botsford, Mary E., San Francisco.
Bucknall, G. J., San Francisco.
Bromley, R. L., Sonoma.
Brown, T. J., Los Angeles.
Chapoye, E. J., Pasadena.
Chisman, E. D., San Francisco.
Cony, E. J., San Francisco.
Chadbourne, E. R., Pasadena.
Dozier, Barton, Los Angeles.
Farper, A. L., San Francisco.
Evans, J. H., Richmond.

Ellis, T. E., Elsinore.
Fasig, H. B., Los Angeles.
Fay, F. G., Sacramento.
Graham, J. W., Lompoc.
Hyman, Solomon, San Francisco.
Hays, E. O., Los Angeles.
Jeonings, G. D., Covina.
Mosely, G. G., Redlands.
Moss, J. M., San Francisco.
Mackinson, H. A., Oakland.
Poore, J. E., Sacramento.
Pritchard, F. H., Colton.
Pitcher, Josephine, Halfmoon Bay.
Peoples, S. Z., Palmdale.
Read, W. P., San Francisco.
Silverberg, Melville, San Francisco.
Taylor, A. W., Santa Barbara.
Van Slyke, D. B., Pasadena.
Wagner, John, San Francisco.
Wrenn, J. Q., Placerville.

COLORADO.

Boatay, F. S., Akron.
Gillespie, Carson, Nederland.
Jackson, F. A., Salida.
Loomis, P. A., Colorado Springs.

Marriages

JOSEPH BIELLO, M.D., to Miss Maria T. DeLuca, both of Philadelphia, February 21.

J. WILLIAM EIDSON, M.D., to Miss Bertha Anne Staley, both of Bourbon, Ind., February 14.

J. HERBERT WADE, M.D., to Miss HELENE HECK, M.D., both of Boonsboro, Md., January 24.

JOY HARRIS, M.D., and Squire G. T. Glascock, both of Greensboro, N. C., February 22.

I. VALENTINE LEVI, M.D., Philadelphia, to Miss Helena Rosenstein of Lancaster, Pa., February 22.

CHARLES M. DUNNING, M.D., Franklin Furnace, N. J., to Miss Isabelle Watt of Hamburg, N. J., recently.

PHILIP HANSON HISS, M.D., New York City, to Miss Caroline Daw, in Brooklyn, N. Y., February 13.

HANNAH C. McCABAN FLEMING, M.D., and William J. Moran, both of Falls City, Neb., at Hiawatha, Kan.

GEORGE W. McCAFFERTY, M.D., Norristown, Pa., to Miss Esta Mae Grove of Stewartstown, Pa., February 18.

ELMER E. BARTELT, M.D., Lamar, Colo., to Miss Nellie Gersbach of Montezuma, Iowa, in Denver, Colo., February 18.

WILLIAM EDGAR WIRT, M.D., Havana, Cuba, to Mrs. Lucy J. Belding of Cleveland, Ohio, at Jacksonville, Fla., February 12.

CHARLES WESLEY BISHOP, M.D., Minneapolis, Minn., to Mrs. Mildred Catherine Werder of Milwaukee, Wis., at Clinton, Iowa, February 20.

Deaths

John E. Bingham, M.D., Jefferson Medical College, Philadelphia, 1873; first president of the Walla Walla Medical Society; for four years a surgeon in the United States Marine Corps, and afterward acting assistant surgeon in the United States Army, in the Nez Perce campaign and in the Spanish-American War; for one term a member of the State Board of Medical Examiners; physician to the state penitentiary; local surgeon at Walla Walla, Wash., of the Oregon Railway & Navigation Company, died at his home at Walla Walla, February 19, from nephritis, aged 59.

Joseph Hils, M.D., McGill University, Medical Department, Montreal, 1873; a prominent physician of Woonsocket, R. I.; a member of the Rhode Island Medical Society and of the Woonsocket District Medical Association; consulting surgeon of St. Joseph's Hospital, Providence, in 1894, and a member of the Woonsocket Hospital staff and surgeon-in-chief since the foundation of the institution in 1888, died at the Woonsocket Hospital, February 23, from nephritis, after an illness of three weeks, aged 56.

John Williamson Palmer M.D., University of Maryland, School of Medicine, Baltimore, 1846; first city physician of San Francisco, in 1849-50; surgeon in the Borneo War, in 1851 and 1852; a Confederate war correspondent during the Civil War; one of the editors of the Century and Standard dictionaries; distinguished as a physician, traveler, litterateur and poet, died at his home in Baltimore, February 26, from senile debility, aged 80.

Joseph P. Bolton, M.D., Jefferson Medical College, Philadelphia, 1890; demonstrator of chemistry and physiology in that institution; a member of the Philadelphia County Medical Society; assistant in the orthopedic and neurological out-patient departments of Jefferson Hospital, died in that institution February 24, a week after an operation for tumor of the brain, aged 66.

James B. Cherry, M.D., Department of Medicine of the University of Pennsylvania, Philadelphia, 1868; a veteran of the Civil War; a trustee of the pauper institutions of Boston in 1904; for several terms medical director of the Department of Massachusetts, G. A. R.; a member of the Fusilier Veteran Association and of the Ancient and Honorable Artillery Company, died suddenly at his home in Boston, February 21, from heart disease, aged 62.

Edwin Geer, M.D., College of Physicians and Surgeons, Baltimore, 1891; organizer and commander of the Maryland Naval Brigade; surgeon to the fire department of Baltimore; formerly coroner of Baltimore County, and assistant quarantine officer of Baltimore; a lieutenant senior grade in the Navy during the Spanish-American War, died at his home in Baltimore, February 25, from septicemia, after a long illness, aged 41.

Samuel Doolittle Brooks, M.D., Berkshire Medical College, Pittsfield, Mass., 1841; superintendent of the New York Juvenile Asylum from 1863 to 1873; for six years medical supervisor of Mount Holyoke Academy, South Hadley, Mass., and for five years superintendent of the Massachusetts State Almshouse, died at his home in Springfield, Mass., February 26, aged 89.

C. Henri Woode, M.D., Howard University, Medical Department, Washington, D. C., 1892; one of the most prominent colored practitioners of Vicksburg, Miss.; for ten years a member of the board of pension examining surgeons; founder and president of the Union Savings Bank of Vicksburg, died at his home in that city, February 26.

Laird M. Woods, M.D., University of Buffalo, Medical Department, 1872; Burgess of Wheatland, Pa., for several terms; for ten years surgeon for the Pennsylvania Road; for several terms coroner of York County, Ore., died at his home in Dallas, Ore., February 12, from septicemia, due to a carbuncle, after a long illness, aged 70.

August Rhoads, M.D., Chicago Medical College, 1873; for thirty years a practitioner of Carthage, Mo.; a veteran of the Civil War; a prominent member and several times an officer of the Jasper County Medical Society, died at his home in Carthage, February 28, from nephritis, after an illness of four months, aged 69.

John T. Coates, M.D., Kentucky School of Medicine, Louisville, 1872; a veteran of the Civil War; for fourteen years a practitioner of Milwaukee, died at his home in that city, February 22, as a result of injuries sustained Sept. 4, 1905, when he was crushed between a dray and a moving railway car, aged 55.

John O. F. Hill, M.D., Long Island College Hospital, Brooklyn, N. Y., 1886; a member of the Kings County Medical Society, and formerly a member of the Coney Island school board; probably the best known physician of Coney Island, died in Connecticut, February 27, after a brief illness, aged 43.

C. E. Boynton, M.D., College of Medicine, Syracuse University (N. Y.), 1888, formerly resident physician at the Onondaga County (N. Y.) Insane Hospital and later a practitioner in Wyoming, Oregon, Washington, California and Utah, died in Redding, Cal., February 12, after a long illness, aged 45.

Sumner Clark, M.D., St. Louis Medical College, 1871; a member of the American Medical Association; one of the most prominent and wealthy physicians of Effingham County, Ill., owner of the Effingham Republican, died at his home in Effingham, March 4, from pneumonia, after a short illness.

Abner C. Calvin, M.D., Jefferson Medical College, Philadelphia, 1878, of Meadville, Pa., died suddenly at the City Hospital, Meadville, from edema of the lungs, February 24, two weeks after a runaway accident in which he was thrown from his buggy and sustained serious injuries, aged 51.

Charles A. Foster, M.D., College of Physicians and Surgeons in the City of New York, 1870, of Newark, Ohio, at one time a member of the faculty of the Ohio Medical University, died from uremia at the City Hospital, Newark, February 21, eight days after an operation for appendicitis, aged 64.

Alfred J. Catellier, M.D., Laval University, Medical Department, Quebec, 1891, a member of the American Medical Association, and one of the most prominent physicians of New Hampshire, died at his home in Berlin, February 17, from heart disease, after a brief illness, aged 38.

Joseph Edgar Wells, M.D., Jefferson Medical College, Philadelphia, 1887; a member of the American Medical Association and of the Kings County (N. Y.) Medical Society; a prominent practitioner of Brooklyn, died at his home in that city, February 26, from heart disease, aged 41.

Benjamin F. Tombs, M.D. (Cleveland (Ohio) Medical College, 1867; a member of the Cambria County (Pa.) Medical Society; a well-known practitioner of Morrellville, Pa., died at his home in Johnstown, Pa., February 19, from nephritis, after an illness of several years, aged 70.

C. W. Salter, M.D. Medical College of Georgia, Augusta, 1879; a prominent physician and planter of Bartow, Ga.; twice a representative of Jefferson County in the legislature, died at his home in Bartow, February 22, from acute gastritis, aged 57.

Hiram A. Peterman, M.D. Eclectic Medical Institute, Cincinnati, 1857; a surgeon in the army during the Civil War, died at his home in Marshall, Mich., February 23, from senile debility following a fracture of the hip eight weeks before, aged 84.

Richard S. Vickery, M.D., assistant surgeon, Second Michigan Infantry, and afterward surgeon in the Civil War; successively assistant surgeon, captain, major and lieutenant-colonel in the regular establishment, died recently in New Jersey.

John V. Nash, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1888, coroner of Sabine Parish, Louisiana, for two terms, died at his home in Many, La., February 23, from nephritis, after an illness of two weeks, aged 46.

Harold F. Thompson, M.D. Tufts College Medical School, Boston, 1905, an interne at the Worcester City Hospital, died in that institution February 19 from pneumonia, following rheumatism, after an illness of less than two weeks, aged 25.

J. H. Giddings, M.D. Castleton (Vt.) Medical College, 1856; a pioneer practitioner of Harrison County, Iowa; surgeon in an Illinois regiment during the Civil War, died at his home in Woodbine, Iowa, February 28, from pneumonia, aged 74.

David S. Allhands, M.D. Eclectic Medical Institute, Cincinnati, 1856; University of Louisville, Medical Department, 1893, of Louisville, died at St. Anthony's Hospital in that city, February 23, from uremia, after a long illness, aged 72.

Edward H. Mayer, M.D. Howard University, Medical Department, Washington, D. C., 1885, the first regular colored practitioner of Columbus, Ga., died at his home in that city, February 24, from pneumonia, after an illness of one week.

John Udolphus Haynes, M.D. Albany (N. Y.) Medical College, 1872, for several terms alderman and member of the board of education of Cohoes, N. Y., died at his home in that city, February 23, after a protracted illness, aged 56.

William Hill, M.D. Jefferson Medical College, Philadelphia, 1856; once United States consul at Sarنيا, Ont.; a prominent practitioner of Bloomington for nearly fifty years, died at his home in Bloomington, Ill., March 1, aged 77.

George K. Harrington, M.D. Bellevue Hospital Medical College, New York City, 1874, for many years a leading practitioner of Jackson, Miss., died suddenly from cerebral hemorrhage in Canton, Miss., February 19, aged 54.

Lawrence G. Mitchell, M.D. University of Maryland, School of Medicine, Baltimore, 1884, Downings, Va., a member of the American Medical Association, died near Sharp's Wharf, Richmond County, Va., February 28, aged 44.

C. T. Simpson, M.D. Medical College of Alabama, Mobile, 1877, formerly of Temple, Texas, and superintendent of the State Insane Hospital, Austin, died at his home in Cananea, Mexico, February 18, from pneumonia.

C. C. Cole, M.D. Ohio Medical University, Columbus, 1896, coroner of Belmont County, Ohio, in 1902, of Bridgeport, Ohio, died at the City Hospital, Wheeling, W. Va., from gall-stone disease, February 25, aged 37.

L. P. Rogers, M.D. Rush Medical College, Chicago, 1876, of Beatrice, Neb., formerly a practitioner of Buffalo, Ill., was instantly killed February 25, at Godfrey, Ill., by falling under the wheels of a passenger train.

Daniel Webster Cooper, M.D. New York University, New York City, 1855, for many years a practitioner of Port Jervis, N. Y., died in Mount Salem, N. Y., suddenly, from heart disease, February 14, aged 74.

William F. Drake, M.D. New York University, New York City, 1889, died at his home in New York City, March 1, from the effects of an overdose of morphia, self-administered for the relief of neuralgia, aged 39.

Thomas Noys Birnie, M.D. College of Physicians and Surgeons in the City of New York, 1880, of Springfield, Mass., died at Orlando, Fla., February 26, from nephritis, after a long illness, aged 51.

Thomas J. Clouse, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1869, died at his home in Galumna, Ohio, from subacute nephritis, after an illness of three days, February 25, aged 64.

Samuel Breitenbach, M.D. College of Physicians and Surgeons in the City of New York, 1848, died at his home in Roxborough, Philadelphia, February 27, after a prolonged illness, aged 80.

Lewis Bieber, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1867, a veteran of the Civil War, died at his home in Phillipsburg, N. J., February 26, aged 61.

S. J. Withers, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1850, a well-known practitioner of Mooresville, Ala., died at Pine Bluff, Ark., February 27, aged 78.

J. Linwood Gunn, M.D. Kentucky School of Medicine, Louisville, 1877, of Ashland, N. C., was thrown from his buggy near Williamson's Mill, N. C., February 22, and instantly killed, aged 45.

Thomas Hill, M.D. New York University, New York City, 1854, surgeon in the Confederate service during the Civil War, died suddenly at his home in Goldsboro, N. C., February 18, aged 73.

Randall Holden, M.D. Baltimore Medical College, 1861, assistant surgeon in the Confederate service during the Civil War, died at his home in Petersburg, Va., February 3, aged 86.

Addison H. Foster, M.D. College of Physicians and Surgeons in the City of New York, 1866, formerly a prominent practitioner of Chicago, died at his home in Oak Park, Ill., March 3.

George W. McConnell, M.D. Eclectic Medical Institute, Cincinnati, 1871, died at his home in Ashland, Ores., from acute gastritis, February 22, after an illness of two days, aged 56.

Adam L. Galbraith, M.D. Medical College of Ohio, Cincinnati, 1890, died at his home in Frankfort, Ohio, February 20, from tuberculosis, after an illness of several years, aged 39.

Thomas Walker Murray, M.D. Jefferson Medical College, Philadelphia, 1885, died at his home in Philadelphia, February 25, from pneumonia, after a short illness, aged 45.

Abel L. Darling, M.D. Eclectic Medical Institute, Cincinnati, 1881, of Kibbourn, Ill., died suddenly at a hotel in Pekin, Ill., from heart disease, February 23, aged 55.

Edward K. Thompson, M.D. Hahnemann Medical College and Hospital, Chicago, 1888, died at his home in Kansas City, Mo., after an illness of four days, February 27, aged 44.

Eli Stoter, M.D. Medical Department of the Western Reserve University, Cleveland, Ohio, 1881, died at his home in Bellville, Ohio, February 27, from lung disease, aged 50.

Stephen L. Breckenridge, M.D. St. Louis Medical College, 1879, a member of the American Medical Association, died at his home in Riverside, Ill., February 21, aged 44.

Augustus L. Gilbert, M.D. University of Buffalo (N. Y.) Medical Department, 1848, died at his home in North Cohasset, N. Y., February 22, from pneumonia, aged 81.

William H. Hinton, M.D. University Medical College of Kansas City, 1896, of Ogden, Utah, died at the Ogden General Hospital, February 19, from meningitis, aged 37.

John D. Mulherson, M.D. Jefferson Medical College, Philadelphia, of Nashville, died at the home of his mother in Brownsville, Tenn., February 18, aged 37.

Stephen M. Harris, M.D. Cooper Medical College, San Francisco, 1890, twice mayor of Grass Valley, Cal., died at his home in that city, February 18, aged 77.

Nicholas D. Young, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1867, died at his home in Youngsville, La., February 8, aged 64.

Leonard P. Aaron, M.D. North Carolina Medical College, Davidson, died at his home in Mount Olive, N. C., from heart disease, after a long illness, aged 32.

Cynthia Singleton-Sheffield, M.D. Eclectic Medical Institute, Cincinnati, 1884, died at her home in Waterloo, Iowa, February 17, after a short illness, aged 60.

Edward M. Allen, M.D. Vanderbilt University, Medical Department, Nashville, 1893, died suddenly at his home in Dayton, Tenn., February 22, aged 35.

J. H. Chandler, M.D. University of Tennessee, Medical Department, Nashville, 1900, of Jackson, Tenn., died in Gibson, Tenn., February 19, aged 35.

J. C. Riley, M.D. Atlanta (Ga.) Medical College, 1891, of Hamilton, Ga., died suddenly at Phoenix, Ariz., February 17.

B. W. Woodburn, M.D. (Thirty-three Years' Practice, Kentucky, 1893), died at his home in Bremen, Ky., February 24, from heart disease, aged 73.

Albert D. Hill, M.D. Albany (N. Y.) Medical College, 1879, died suddenly at his home in Chicago, March 4, from heart disease, aged 57.

C. D. Osburn, M.D. Jefferson Medical College, Philadelphia, 1886, died at his home in Wilsonville, Ore., February 19, from acute gastritis.

George L. Newcombe, M.D. Harvard University Medical School, Boston, died at his home in North Scituate, Mass., February 21.

N. Lee Howison, M.D. State University of Iowa, Medical Department, Iowa City, 1882, died at his home in Bogata, Texas, February 19.

David McClenahan, M.D. Starling Medical College, Columbus, Ohio, 1863, died at his home in Cedar Rapids, Iowa, February 25, aged 86.

Death Abroad.

S. S. Rosenstein, M.D., professor of experimental pathology and pathologic anatomy at Leyden, died January 31, aged 74. He was a native of Berlin and privat docent at the university until he accepted a call to Holland in 1865. His greatest work was a treatise on pathology and treatment of kidney affections, 1863, which has been translated into several languages. Among his other numerous works are several on diabetes, cirrhosis of the liver, etc., and his pupils, de Jong and de Haan, have also made notable contributions to the pathology of digestion and metabolism.

Book Notices

PSYCHIC TREATMENT OF NERVOUS DISEASES. P. DuBois. Translated and edited by S. E. Jelliffe, M.D., Ph.D., and W. A. White, M.D. Cloth. Pp. 466. Price, \$2.00 net. New York: Funk & Wagnalls Co. 1905.

In these days when so much has been said and is still being said in regard to suggestion in medical treatment this translation of Professor DuBois' work on the psychoneuroses and their moral treatment is timely. It differs decidedly from much of the literature on the subject that is so familiar to us. There is no claim of the virtues of hypnotism. The author's methods are not mysterious, but are based on common-sense principles, accepting as he does the amenability of a large class of diseases to mental influences rationally employed. In so far, however, as it is a protest against physical methods in these special disorders it may not command absolute agreement with its demands on the part of all its readers. Every skilled practitioner must be well aware of the value of moral treatment in many cases, and there are few, if any, who do not consciously use it in their practice. A very large number will, nevertheless, find the work very suggestive and profitable reading, even if they can not follow the author in all of his views.

The first six or seven chapters, comprising about one-fifth of the volume, are not strictly medical, but rather psychological. In these the author develops his ideas that have led him up to the therapeutic position he has taken and which he considers an essential introduction to the more practical part of his work. It does not follow, however, according to his own statement, that it is necessary for the success of his methods that the physician employing them must be like him, a materialistic monist and determinist, and those, therefore, who may find themselves disagreeing with his very pronounced opinions may still derive profit from his book.

The psychotherapy which he calls rational is addressed directly to the reason of the patient, and depends very largely on the tact and sympathy of the physician—fully as much as on his faith in his theories and methods. The patient must be inoculated with the idea that his case is a curable one, his exaggerated susceptibilities must be toned down and, while DuBois does not specially favor the use of drugs and remedies their use in many of these conditions, he does not neglect the advantages of certain physical measures such as environment, etc. Thus he employs a modified Weir Mitchell method, without any special dependence on electricity and massage measures, and places the principal stress on purely moral treat-

ment with rest and good nutrition in a well-regulated sanitarium. In fact, he rather condemns, for many cases, the employment of even elaborate clinical examination methods as tending to produce a mental condition unfavorable to the psychic treatment. He employs his treatment not only in cases clearly hysterical and neurasthenic, but also in conditions that are sometimes considered organic, such as mucous or so-called membranous colitis, which, according to his observation, is mainly the result of habitual constipation. It is probable that some of our specialists in rectal diseases may think his observation imperfect in some of these cases.

Take it as a whole, however, Professor DuBois' work makes a very good showing for moral treatment in a very large class of disorders not dependent on determinable permanent organic changes. Whether every practitioner will be able to go his length in the rejection of drug medication and certain physical agencies is, perhaps, a question, and it certainly will require more than usual diagnostic skill to exclude a possible element of organic disease in many of these cases. The book is one, however, that few judiciously minded physicians can read without profit. It is beautifully written and the translation seems to very fairly reproduce the spirit as well as the accurate text of the original. The obtrusiveness of the author's religious heterodoxy, which is not an essential feature in a work of this kind, might well have been omitted. But Professor Dejerine says in his preface that DuBois is "a man with convictions," which he is not afraid to express in religious as well as in other matters. We have also the same authority as evidence that Dr. DuBois has resolutely and thoroughly carried out his ideas in his therapy and as it here appears with great success.

Miscellany

Diseases of the Indians.—At a joint meeting of the Medical and Anthropological societies of the District of Columbia, Dr. Alex. Hrdlicka read a paper on this subject. His information was derived partly from personal observation and partly from data furnished by physicians in the Indian service. He said that on the whole the health of the Southwestern and North Mexican uncivilized Indians is superior to that of the whites living in larger communities. The Indian's advantage lies chiefly in the greater freedom from those morbid conditions that arise through defective heritage; from those that in the white race frequently accompany teething, puberty, menstruation, gestation, menopause and senility, and from malignant growths; while the only disadvantage of the Indian consists in a possibly lesser resistance to some of the contagious diseases, notably smallpox and measles. He stated that pathologic conditions of the blood are rare, but that anemia is occasionally met in the later stages of malaria or in a slight degree in some of the taller schoolgirls who have become debilitated. Occasionally the thyroid degenerates into goiter. The lymph glands appear to be the seat of only one affection, and that scrofula; even this is rare. The prostate was found enlarged in only a few instances. Affections of the mammary gland are much less common than in white women. Diseases of the circulatory system are very infrequent but, on the other hand, respiratory affections are relatively common and cause numerous deaths. Varicose veins are rare, as are hemorrhoids. Disorders of the digestive apparatus, he states, are more common than any other disease of the Indians, not except in infants they are rarely serious. Typhoid is uncommon, though forms of bloody diarrhea or dysentery, often probably of malarial origin, attack Indians of certain localities, especially in the lower parts of Mexico. Intestinal parasites are seldom heard of. Kidney disorders in pregnancy, and eclampsia are rare. Diseases of the skin are chiefly limited to eczema, favus or ulcers, in the children, acne in young adults, and ulcers due to neglect in the older. Headache is common, but epilepsy, insanity and paralysis are rare, and idiocy is almost unheard of. Strabismus is very rare. Narrowing of the lids from chronic conjunctivitis is common in old people. Corneal ulcerations and opacities are not infrequent and occa-

State Boards of Registration

COMING EXAMINATIONS.

MAINE State Board of Registration of Medicine, City Building, Portland, March 13. Secretary, Wm. J. Maybury, Seco.
CONNECTICUT Medical Examining Board, City Hall, New Haven, March 13-14. Secretary, Charles A. Tuttle, New Haven.
MASSACHUSETTS Board of Registration in Medicine, State House, Boston, March 13-14. Secretary, Edwin B. Harvey, Boston.

Alabama Report.—Dr. W. H. Sanders, chairman of the State Board of Medical Examiners of Alabama, reports the written examinations held by the county and state boards of Alabama during the year 1905. The number of subjects examined in was 10; number of questions asked, 6 to 10 in each branch or subject; percentage required to pass, 75. The total number of candidates examined was 154, including 14 non-graduates, of whom 131 passed and 23 failed, including 1 osteopath. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Medical College of Alabama, (1903) 92; (1904) 78, 81, 82, 83, 92; (1905) the grades of 75, 80 and 81 were reached by one each, 82 and 83 by two each, 84 and 85 by one each, 86 by five, 87 by three, 88 by two, 89 by three, 92 and 93 by two each, and 95 and 98 by one each.			
Leonard Med. Coll.	(1905) 76, 82, 83		
Chattanooga Med. Coll., (1902) 80; (1905) the grade of 76 was reached by three, 82 by one, 83 by two and 84 and 88 by one each.			
Memphis Hosp. Med. Coll., (1899) 82; (1904) 88; (1905) 78, 85, 92.			
College of P. and S., Atlanta (1905) 76, 82, 87, 88			
Vanderbilt University (1896) 84; (1905) 84, 84, 85, 95			
Birmingham Med. Coll. (1905) 80, 85, 85, 87, 88, 91, 91			
Meharry Med. Coll. (1905) 76, 78, 78, 82, 83, 86, 86			
Grant University (1905) 79, 86			
Knoxville Med. Coll. (1901) 79			
University of the South (1904) 82; (1905) 83, 90, 91			
Cornell University (1905) 89			
University of Virginia (1897) 87; (1903) 86; (1905) 85, 88			
University of Missouri (1904) 88			
Rush Med. Coll. (1889) 91; (1904) 86

Georgia Coll. of Eccl. Med. and Surg. (1897) 22			

* This school merged with Indiana Eclectic Med. coll. in 1886.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending March 3, 1906:
Kirkpatrick, Thos. J., asst.-surgeon, granted thirty days' leave of absence. Reported for treatment at Army General Hospital, Washington Barracks, D. C.
Thorp, Charles W., contract surgeon, returned to Fort Ethan Allen, Vt., from sick leave.
Enders, William J., contract surgeon, left Fort Morgan, Ala., on leave of absence for one month, ten days.
Wall, Francis M., contract surgeon, left Fort Oglethorpe, Ga., on leave of absence for eight days.
Whitney, Jewell C., dental surgeon, left Fort Wright, Wash., for duty at Fort Stevens, Oregon.
Ware, William H., dental surgeon, returned to duty at Fort Logan, Colo., from leave of absence.
Long, Charles J., dental surgeon, left Fort Snelling, Minn., for duty at Fort Harrison, Mont.
Rietz, Huzo C., dental surgeon, left Fort Sheridan, Ill., for duty at Fort Thomas, Ky.
Bailey, Edward, contract surgeon, granted leave of absence for four months.

sionally cataract is seen. Defect of the palate in a full-blooded Indian has never been seen and only one case of minor hare-lip was observed. Except syphilis and gonorrhea, diseases of the sexual organs are seldom indicated by any external sign, among those who approach or are approached by a physician. Notwithstanding the unhygienic condition of the Indians, neither gonorrhea nor syphilis is commonly attended by great destruction of tissues or by grave general consequences. Signs of hereditary syphilis in children are uncommon. Syphilis in the Indians affects the bones as it does in the whites; therefore, if syphilis existed before the Spaniards reached this country, signs of it should be at least occasionally discovered in the ancient burials. But the bones of the old burial places are, as a rule, free from any sign of the disease; and this is true of the bones from ancient graves in California, northwest coast and other localities, exclusive of some mounds. It is difficult to see, if the disease existed before the whites came, how, with the well-known wide intercourse among the Indians, whole great regions could escape it. It may be remarked that it is also absent in the older burials from Peru and other localities in South America.

Ultimate Fate of Tetany Patients.—At a meeting of the Vienna Medical Society, January 25, von Frankl-Hochwart reported the results of recent investigation into the present condition of all the patients with tetany whom he has had under his care. He was able to learn the fate of 55 out of the total 160. Eleven had died, their lives considerably shorter than the average for their circumstances and occupations. It is possible, he thinks, that the tetany may have induced a constitutional weakness which rendered the subjects less resistant to mild infectious diseases. Of the remaining 44, letters were received from 7, and 37 were personally examined. Only 14 of the entire number are healthy, with 4 only partially so; 19 present tetanoid conditions, some exhibiting a kind of chronic debility suggesting myxedema, and 7 suffering from recurring tetany, the attacks coming on most frequently in the winter months. In none of the cured cases is there enlargement of the thyroid, but it is frequent among the others. One of the tetany patients has a child who also exhibits tetany. His experience has been that the epidemics of tetany occur during a few years at a place and then subside to crop up somewhere else. He preaches that the prognosis of tetany is not so favorable as generally taught, the ultimate findings in his 55 cases having materially modified his views. *Die Wien. klin. Wochschr.* for February 8 contains a report of the meeting.

Fatal Suprarenal Hemorrhage from Stroke.—Prof. A. Sodré of Rio has been making a special study of "thermic fever," "febre de calor" as he calls it, the result of sunstroke or heat-stroke. On several days in last December there were as many as 10 cases a day at Rio de Janeiro. The autopsy findings in one case, reported by S. Moniz in the *Revista Medico-Cirurgica do Brazil* for December, showed that death was due to hemorrhage from the suprarenal capsules. The patient was a man of 30, working out of doors when overcome by the heat. His temperature was 41.6 C. (107 F.) and he was in convulsions when first seen. General asthenia and intense thirst continued for four days, the heart action weak but distinct, no albumin or sugar in the urine. Slight improvement was noted the fourth day, but the patient died suddenly while at stool. The viscera were found comparatively normal with the exception of the suprarenal capsules which had ruptured from the pressure of a large hemorrhage.

Queries and Minor Notes

HAGER'S CORYZA REMEDY.

A correspondent asks about Hager's coryza remedy. Otorhinolaryngeal antiseptic (Hager) is no doubt the preparation intended. A small wide-mouth vial is filled one-third full of the following solution:

R. Phenolis.....	5grs.	10
Alcoholis, ss.....		12
Aque ammoniac.....	3iii	
Aque dest.....	3v	20

The vial is then filled with a plug of cotton for inhalation in coryza, catarrh, and similar affections.

Long, Stephen M., contract surgeon, granted leave of absence for one month.

Stuckey, Harrison W., contract surgeon, returned from temporary duty at Fort Assiniboine, Mont., to Fort Snelling, Minn.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending February 3, 1906:

Feld, J. G., ordered to the Bureau of Medicine and Surgery, Navy Department.

Chappelear, F. D., acting asst.-surgeon, appointed acting assistant surgeon from Feb. 28, 1906.

Xash, F. S., surgeon, detached from the *Oregon* and ordered to the *Rainbow*.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Feb. 28, 1906.

Pettus, W. J., assistant surgeon-general, granted leave of absence for one month, from March 1.

Macruder, G. M., surgeon, on expiration of leave of absence to proceed to Portland, Ore., and assist in the service.

Nydegger, J. A., asst. surgeon, to proceed to Perth Amboy, N. J., for special temporary duty, on completion of which to rejoin station at Stapleton, N. Y.

Coker, L. E., P. A. surgeon, granted one day leave of absence under Paragraph 189 of the Regulations.

Korn, W. A., P. A. surgeon, granted leave of absence for fourteen days from March 2.

Long, J. B., P. A. surgeon, granted seven days' leave of absence in December, 1905, under Paragraph 191 of the Regulations.

Burkhalter, J. T., P. A. surgeon, on being relieved by Asst.-Surgeon R. D. Spratt to proceed to Ellis Island, N. Y., reporting to the medical officer in command for duty.

Spratt, R. D., asst.-surgeon, relieved from temporary duty at Mobile, Ala., and directed to proceed to Brunswick quarantine station and assume command of the service, relieving P. A. Surgeon J. T. Burkhalter.

Delgado, J. M., acting asst.-surgeon, granted four days' leave of absence from February 13, under Paragraph 210 of the Regulations.

Kortz, W. E., acting asst.-surgeon, granted leave of absence for thirty days from January 1 on account of sickness.

Richmond, N. D., acting asst.-surgeon, granted leave of absence for fourteen days from January 27, on account of sickness.

Safford, M. V., acting asst.-surgeon, granted three days' leave of absence from February 17, under Paragraph 210 of the Regulations.

O'Gorman, T. V., pharmacist, relieved from duty at New Orleans, La., and directed to proceed to Memphis, Tenn., reporting to the medical officer in command for duty and assignment to quarters.

Scott, E. B., pharmacist, granted two days' leave of absence from February 21, under Paragraph 210 of the Regulations.

BOARD CONVINED.

Board convened to meet at the Bureau, Washington, D. C., February 24, for the purpose of making a physical examination of an officer of the Revenue Cutter Service. Detail for the board: Assistant Surgeon-General W. J. Pettus, chairman; Assistant Surgeon J. W. Trask, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended March 2, 1906:

SMALLPOX—UNITED STATES.

California: Los Angeles, Feb. 10-17, 5 cases; San Francisco, 12 cases.

Delaware: Wilmington, Feb. 17-24, 2 cases.

District of Columbia: Washington, Feb. 10-24, 9 cases, 1 death.

Florida: Jacksonville, Feb. 17-24, 5 cases.

Kentucky: Lexington, Feb. 15-22, 1 case.

Louisiana: New Orleans, Feb. 17-24, 11 cases.

Maryland: Baltimore, Feb. 17-24, 7 cases.

Massachusetts: Boston, Feb. 17-24, 1 case.

Michigan: Ann Arbor, Feb. 10-24, 1 case.

Ohio: Cincinnati, Feb. 16-23, 2 cases.

Tennessee: Memphis, Feb. 17-24, 8 cases, 1 death.

Virginia: Petersburg, Feb. 1-26, 17 cases.

Wisconsin: Appleton, Feb. 17-24, 2 cases; Green Bay, 3 cases.

SMALLPOX—FOREIGN.

Africa: Cape Town, Jan. 6-20, 16 cases.

Canada: New Brunswick—Kings County, Feb. 18, present;

Queens County, present; Simsbury County, present; York County, present; Toronto, Feb. 10-17, 2 cases; Winnipeg, 1 case.

Chile: Iquique, Jan. 20-27, 1 death.

China: Shanghai, Jan. 18-20, 1 case, 1 death.

Ecuador: Guayaquil, Jan. 28-Feb. 4, 5 deaths.

France: Paris, Feb. 3-10, 11 cases.

Gibraltar: Feb. 4-11, 5 cases, 2 deaths.

Great Britain: Bristol, Feb. 3-10, 1 case.

Greece: Athens, Jan. 2-10, 7, 5 cases.

India: Bombay, Jan. 25-30, 10 deaths; Calcutta, Jan. 13-20, 55 deaths; Karachi, Jan. 21-28, 9 cases, 3 deaths; Madras, Jan. 20-26, 22 deaths; Rangoon, Jan. 13-20, 38 deaths.

Italy: General, Feb. 1-8, 1 death; Rome, Dec. 16-23, 1 death.

Russia: Moscow, Jan. 20-Feb. 3, 12 cases, 1 death; Odessa, Feb. 3-10, 23 cases, 1 death; St. Petersburg, Jan. 27-Feb. 3, 4 cases, 3 deaths.

Spain: Barcelona, Feb. 1-10, 5 deaths; Seville, Jan. 1-30, 11 deaths.

Turkey: Alexandretta, Jan. 27-Feb. 3, 20 cases, 4 deaths; Constantinople, Jan. 28-Feb. 11, 11 cases.

YELLOW FEVER—FOREIGN.

Cuba: Habana, Feb. 11, 1 case.

Ecuador: Guayaquil, Jan. 28-Feb. 4, 9 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Jan. 17-20, 13 deaths; Madras, Jan. 20-26, 2 deaths.

PLAGUE—FOREIGN.

India: General, Jan. 13-20, 4,652 cases, 3,938 deaths; Bombay, Jan. 23-30, 62 deaths; Calcutta, Jan. 13-20, 32 deaths; Karachi, Jan. 21-28, 7 cases, 6 deaths; Madras, Jan. 20-26, 3 deaths; Rangoon, Jan. 13-20, 23 deaths.

Russia: Province of Astrachan, Dec. 25-Jan. 2, 8 cases, 5 deaths.

Medical Organization

Good Conditions in Texas.

Dr. DAVID R. FLY, Amarillo, Texas, one of the councilors of the State Medical Association of Texas, under date of February 23, writes:

"I find that Dr. McCormack's system of holding public meetings is a marvelous success. I find that the securing of the interest and co-operation of the intelligent laymen to be a strong factor in the lining up and settling of local animosities among the profession. It is remarkable how quick the intelligent public seem to grasp the situation and declare themselves ever ready to lend their support and co-operation in all of our legitimate reforms. I have been very agreeably surprised in the amount of interest and sympathy shown to me in the trials and tribulations of my councilor work by the thoughtful and progressive laymen."

Judging from newspaper clippings that have been sent us from Dr. Fly's district, he is one of the active councilors and is doing much good, not only in organizing societies in his district but in stimulating them to active work. He follows the lead of Dr. McCormack in having meetings to which the public is invited, which are evidently doing good, developing a better feeling between the public and the profession. Undoubtedly this is an excellent thing to do. What is needed to-day is for the profession and the public to get closer together, and for those who write in the newspapers on medico-sociologic subjects to know more of what the profession is doing. One of the best ways to bring about this better feeling is by having these open meetings, allowing some one to represent the public on the program.

Society Proceedings

BOSTON MEDICAL LIBRARY MEETING.

Held Feb. 14, 1906.

Dr. GEORGE W. GAY in the Chair.

The Sanitary Hygiene of the Japanese Army.

CAPTAIN CHARLES LYNCH, Asst. Surgeon, U. S. A., was assigned as medical observer in the recent Russo-Japanese war, and was with the Japanese eleven months, both in Japan and in Port Arthur. He described the organization of the Japanese army, with its active force, in which each man serves three years, and its reserve force. There is a ministry of war with several departments, of which the medical department is one, co-ordinate with the others. The unit is the division. Usually there were three divisions to an army. Each division maintained its communications with home when in the field. There is no quartermaster's department. The system proved a good one in war. Large numbers of men were sent forward at once, fully equipped.

The medical personnel consisted of military surgeons, men who make a specialty of the subject and who make preparations for war in time of peace. These are on the active list, and ten are assigned to each regiment. This is too many for times of peace, but not enough for war. Therefore, there is a reserve medical staff. These men must have seen actual service, but practice at their homes, except during the maneuvers held regularly every year. These reserve medical officers did well. At the outbreak of the war the active list were assigned to administrative duties. The demand for reserve men was so great that civilians were needed. These men passed an

examination and a service of four months in a hospital. They were to be employed in hospitals only, but this was not always possible, and hence their service was not wholly satisfactory. Reasons for this were that they asked for things not usually provided, were not hardened to camp life and were not respected by the troops as were the regular active and reserve surgeons. In spite of this large medical staff located at the front, along the lines of communication and at the bases, there were not enough.

The surgery of Japan is not strictly up to date. There is no great need of it. Japanese medical students rarely study surgery abroad, but they do give much attention to pathology and bacteriology. The surgeons always do things the easiest way. Confusion reigns in the operating rooms. They make large use of the microscope, however, and use medicines freely. By the offer of a good salary they try to attract to the regular active list good men, and they are given adequate rank to secure a right to their opinions. At the head is a surgeon with the rank of lieutenant general. The chief executive is a major general, being one of three in an army. Thence on down the surgeons of a regiment rank as captains. Each of these men must have spent at least one year in the Army Medical School. Here they are encouraged by special courses to become specialists along some particular line. They are allowed to do some outside work as consultants. Promotion is partly by selection. The reserve surgeons are promoted on proof of ability. They are about the equals of their brethren in civil life.

Apothecary officers are graduates of a college of pharmacy. Their highest rank is colonel. There were large numbers of them in the war and they did good work.

There is no hospital corps. At home civilians are hired. In the regular army, men are instructed in hospital work in each company. These soldiers were the chief nurses and they were well disciplined, though not much trained. They did well at the first. Female nurses are practically confined to the Red Cross. Some regular officers were detailed to attend to matters requiring immediate expenditure, among them being a few line officers. In time of peace four men in each company are trained as bearers.

The Red Cross of Japan, which renders voluntary aid, is the best in the world. It has over a million supporters and an income of more than 8,000,000 yen. It furnishes mainly personnel and not materials. Its work is wholly at the bases and along the lines of communication, hospital ships, etc. Each relief detachment consisted of two physicians, one pharmacist, two chief nurses and twenty nurses or attendants. There were 152 such detachments, thirty-two being along the lines and in Korea, thirty-eight in the great army hospitals and the rest scattered. At the end of 1905 they had 4,700 male and female nurses and attendants and had expended over \$2,500,000. Their nurses are the best in Japan, though not equal to ours.

The Ladies' Volunteer Nurses' Association supplemented the Red Cross. Germany, too, aided. Much medical advice by prominent men in the profession outside of the army was offered free and gladly accepted. Many men, professors in the medical schools and of like standing, acted as consultants.

All matters pertaining to the health of the army, whether sick, wounded or apparently well, were made subjects of strict rules. Most of the medical supplies were prepared at Tokio, sent to Dalny and thence forwarded. The quality was carefully inspected and noted, being determined by frequent analyses. Transportation was ably maintained. Hospital buildings were erected very rapidly. Contracts for such buildings are made with all the specifications to be fulfilled if they are needed and only two or three days are necessary, therefore, for their practical completion.

The Japanese appreciate the importance of hygiene, and public sentiment supports the enforcement of strict rules. Whoever comes home from the front suffering from a preventable disease is disgraced. They maintain three requirements—physical fitness, education and supervision. The physical standard is high, yet few are rejected.

Sanitary instruction of officers is not necessary. They are all informed, having learned in schools and colleges. A pamphlet, "Health Rules for the Use of Soldiers in Time of War," is provided for the common soldiers, three or four to every company. They are told of the risks and an appeal is made to

their patriotism. There are directions as to cleanliness, physical training and exercise. They have a hard drill, including much running. Special training in sanitation is given the officers, who have executive functions in these matters as well as advisory ones. The division chief surgeons are the real chief inspectors. The army chief surgeons follow them up and civilian specialists are often called in. Boards of health are established, who seek to rid the army of the unfit. Even field hospitals are equipped with microscopes and laboratories far toward the front. Typhoid fever was less common and dysentery more frequent. There were many diseases common among the Chinese of Manchuria, like cholera and malaria, which were thus kept out of the Japanese camps.

The soldiers were well fed. Rice was the bulk of the ration, being brought from Japan. Little meat, plenty of fruit, sometimes barley in place of rice, some saké and tobacco—the total ration being capable of 2,580 calories. The army is better fed than the people at home. Good water is always sought, analyzed frequently, both chemically and bacteriologically, and in a great majority of cases is boiled before being used—sometimes twice boiled. This boiled water was conveyed in carts holding sixty liters, two for each company. Some use was made of special tablets for purifying the water, but unsuccessfully. More valuable were filters, by which means they did do something in cutting out bacteria. Once the water supply was selected, every unauthorized person, whether native or soldier, was kept away from it.

In the barracks earthen jars were provided for the dejecta, regularly cleansed. In Manchuria large pits were provided. The Chinese were everywhere very filthy. The habits of the Japanese were good. Saké rarely made them drunk. There was little license. Bathing was common. They took good care of their feet, though their shoes were very bad. The best of rules were made and enforced. A monthly physical examination of the soldiers was made. They tried to prevent the water-borne diseases and were most successful. Such patients were isolated to avoid contact as carefully as if they had smallpox. They were screened, carbolic acid was used freely, and also antiseptics for hands and dishes. Special precautions to keep flies from meats and from bedpans were taken. As fast as necessary they were sent back toward the base.

Typhoid fever and dysentery are endemic in those regions, but the Japanese had only one-sixth as many cases as the Russians. This, too, in spite of the fact that they made large use of the Chinese houses. Infection from urine was not considered or proved to be of great importance. There was a constant use of creosote pills, the boxes of which were marked: "To defeat the Russians, take one pill three times a day." Typhus is always present in Manchuria and was isolated in the same way. Beriberi was the great and terrible scourge of the Japanese. Much study was devoted to it and three different germ causes were discovered. None of them was proven to be the cause. It is not promoted by any special diet, but seems to be like typhus, taking its origin in crowded conditions. It was the cause of 40 to 50 per cent. of all the sickness in the army, and often preceded other diseases. Smallpox was rare because of compulsory vaccination. This is done in Japan within 100 days of birth, at the age of 12 or 13 and again at time of conscription. Two or three attempts are required, if necessary. In 1905 a general revaccination was practiced. Japanese virus is good.

Tuberculosis was common. It spread because they do not use modern methods of sanitation for its treatment. Diphtheria was not rare, but there was no measles, mumps nor scarlet fever. Recurrent fever occurred only rarely and was isolated. Erysipelas and tetanus were even rarer. Leprosy is frequent in Japan, but was not met in the army. Influenza was common, but not severe. Manchurian fever seems to be a combination of influenza and typhoid. Influenza was not isolated. Cerebrospinal fever and malaria were rare. There were few venereal cases. Prostitutes were segregated and regularly examined, as in Japan. Trachoma, so common in Japan, was not met in the field. As a whole, the medical department did remarkably well. The records made are very complete and sometime they may be given to the world.

In December, 1905, it was reported that so far in the war there had been killed in action 43,219; wounded in action,

153,673; missing, 5,081; injured not in action, 16,456; sick or died from sickness included 203,207, with 17,860 cases of contagious diseases besides. This makes the disability from wounds and from disease about equal—a very remarkable result.

The medical methods employed are much like ours. They are prone to allow patients to sit up, which was especially bad for the beriberi hearts. The mortality from typhoid was 7 to 10 per cent.; from dysentery, 15 to 17 per cent. Most of the wounds were from rifle balls, though the number from shells, especially shrapnel, was unusually large. Hand grenades, too, were the causes of many terrible wounds. Bayonet wounds constituted not even 1 per cent. of the total. The proportion of killed to wounded was as 1 to 4, and of the wounded 16 per cent. died. Bone wounds suppurred almost invariably. They had a bad "first aid" package—compresses were small, the bandage was insufficient and the cloth cover was not impervious to water. There were few deaths from primary hemorrhages, but many frost-bites. To summarize: Their success seems due to good diagnosis, Red Cross aid, medical skill, prompt aid, no confusion, good preparation in time of peace, large personnel, free expenditure of money, good hygiene and readiness to learn by experience.

NEW YORK PSYCHIATRIC SOCIETY.

Regular Meeting, held in New York, Dec. 6, 1905.

Insanity as a Result of Hysterotomy and Oophorectomy.

The paper on the above subject, read by Dr. Graeme M. Hammond, New York, appears in this issue of THE JOURNAL, pages 713 and 714.

DISCUSSION.

DR. G. H. KIRBY, said that he has seen eight cases in which the psychoses seemed to be more or less directly connected with operations on the generative organs. In four of these cases it was impossible to determine whether the ovaries had been removed; in the remaining four they were undoubtedly removed.

DR. A. MEYER doubted whether it is wise to say that only congenital conditions predispose to the psychoses since it is probable that individuals with a fair start in life can undergo constitutional changes which will predispose to a mental breakdown. As a rule, the nature of the psychoses correspond to the constitutional make-up of the individual.

DR. M. C. ASHLEY thought that it is impossible to state definitely that the psychoses in any given case is the result of an operation. He has seen a number of instances of insanity which were attributed to operations on the reproductive organs, and he has also seen many operations performed that were not followed by a psychosis. On the other hand, profound mental shock has been attributed as a cause of psychosis. Why, then, says Ashley, should not all patients sustaining similar shocks and patients operated on, develop a psychosis unless there is some inherent weakness or predisposition to insanity in those who do become insane.

DR. L. P. CLARK thought that the occurrences of insanity after operation indicates the existence of a primary constitutional defect, and that the exhaustion, fatigue, and worry previous to the operation can not be regarded in any other light than as exciting factors of insanity.

DR. C. F. MACDONALD coincided with the position taken by Dr. Hammond with reference to the etiologic importance of heredity in these cases. He thinks that it is rare, indeed, that a surgical operation of so serious a nature as oophorectomy causes insanity, except in individuals who have an unstable mental and nervous organization, whether inherited or acquired. Only in exceptional cases does insanity follow surgical operations or severe injury, even injuries of the head. Physicians are too much in the habit of seeking for some incident in the life of the individual which may be assigned as the cause of the mental disorder. MacDonald says that he always looks for predisposing and not exciting causes. Alcohol, for example, rarely causes insanity, except in persons who are predisposed thereto. There must be a predisposition to the disease before the so-called exciting causes can become operative. The only way in which exciting causes can become operative is by under-

mining the general health and thus bringing about a condition of malnutrition of the brain which predisposes the individual to a true psychosis.

DR. W. HIRSCH does not think that the ovaries have any physiologic function, except the sexual function; hence removal of the ovaries can not produce insanity any more than any other operation can. Of course, the shock following oophorectomy may be much greater than that following other operations, but the psychosis following it holds that traumatic psychosis is a clinical entity, one which can be diagnosed readily. He agreed with the previous speakers that a perfectly normal brain can not acquire psychosis after any operation, unless it is an organic trauma to the brain, or that there exists a previous disposition to psychosis. He did not agree with Dr. Hammond that a normal man can ever become a paranoiac. The mind of a paranoiac never was a normal one, even if the paranoia did not manifest itself in early life.

DR. E. A. MACDONALD is convinced that operations on the uterus or ovaries have very little specific importance in the production of insanity. He has seen a few cases of postoperative insanity, but in these cases the insanity was due to the shock incident to the operation.

DR. A. M. HAMILTON agreed with the essayist and the previous speakers. He thinks that the profession has a duty to perform, that of educating or at least cautioning those members of the profession who not only wrongly associate neurosis and actual organic diseases, but psychosis as well, with various bodily ailments and defects.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Treatment of Eczema.

A correspondent writes that he has a patient, otherwise healthy, who is afflicted with eczema, but he does not state the variety.

INTERNAL MEDICATION.

In acute eczema—blue mass or compound cathartic pill, followed next morning by a saline laxative. Natural mineral waters are useful, such as the Hathorn, Carlsbad, Hunyadi Janos or Friedrichshall. When both iron and the sulphate of magnesium are indicated the following may be used:

R. Magnesii sulph.	ʒii	60
Acidi sulphur. dil.	ʒiii	8
Ferri sulph.	ʒss	65
Sodii chlor.		
Tinct. card. comp.	ʒi	4
Aque dest.	Oss	250

Filtera. Sig.: A tablespoonful before breakfast in a tumblerful of cool or hot water.

In case of renal derangement diuretics are indicated, and in gouty cases, colchicum and Vichy water.

When both diuretics and alkalies are indicated the following may be used:

R. Magnesii sulph.	ʒss	15
Magnesii carb.	ʒi	4
Tinct. colchici	ʒss	2
Olei menth. pip.	m. ii	12
Aque dest.	ʒvi	180

LOCAL MEDICATION.

The following is a useful lotion:

R. Acidi carbonici.	ʒii	265
Zinci oxidi	ʒi	4
Glycerini	ʒiii	8
Aque calcis q. s. ad.	ʒviii	240

In this formula, when carbonic acid does not act favorably, dilute hydrocyanic acid may be substituted. Tragacanth mucilage may be used instead of glycerin, or both may be omitted and half the amount of lime water may be replaced by an equal quantity of elder-flower water.

R. Acidi hydrocyanici dil.	3ss ii	2-8
Zinci oxid.		
Calamin. aa.	3i	4
Aque calcis		
Aque sambuci, aa.	3iv	120
Or:		
R. Acidi carbolic.	3ss ii	2-8
Bismuthi subnit.	3i	4
Pulv. tragacanth.	gr. x	26
Aque calcis	3viii	240

WEEPING ECZEMA.

In the so-called weeping eczema the following is useful:

R. Tinct. opii	3ss	15f
Liquoris plumbi subacetatis dil q. s. ad.	3viii	240

To this may be added glycerin, boric acid to saturation, zinc oxid or other powder to be left on the skin as a deposit; or from half to one ounce of the tincture of camphor, if this drug is well borne and if a decided antipruritic effect is desired. A saturated solution of boric acid to which has been added 2 per cent. or more of glycerin or tragacanth mucilage is an excellent application in moist eczema and in the suppurating forms.

Hyde states that for the subacute and indolent stages mildly stimulating and stronger antipruritic lotions containing tar, carbolic acid, menthol, camphor, chloral and alcohol may be used, but that they should be tried cautiously and diluted at first. They generally give best results when applied for a few minutes at a time, several times a day.

In some acute inflammatory cases, Lassar's paste gives good results:

R. Zinci oxidi		
Amyli. aa.	3ii	8
Petrolati.	3iv	15

To this is generally added from 3 to 10 grains of salicylic acid.

Another paste which gives good results is Dühring's paste:

R. Zinci carb.	3i	4
Acidi salicylic.	gr. x	65
Petrolati.	3ii	8
Cerat. plumbi subacetat.	3vi	24

Hyde and Montgomery recommend the following:

R. Bismuthi oxidi	3ss	2
Vaselin.		
Olei olivæ, aa.	3ss	15
Cere alb.	3iiss	6
Olei rosæ q. s.		

Stelwagon states that diachylon ointment, if well and freshly prepared, is soothing and mildly astringent, but that it is difficult to obtain a good preparation. If this ointment is not fresh, irritation often follows its application.

Unsalted Diet in Scarlet Fever.

Dufour, Pater and a number of other physicians have been studying the effect of restriction of salt in the diet of scarlet-fever patients. They find that it is well tolerated and protects against kidney trouble as well as a strict milk diet. If there is a tendency to albuminuria at first, it soon subsides. The children all increased in weight on the mixed unsalted diet as soon as the fever declined. The general impression was that the course of the disease was shortened and the patients rendered more resistant to intercurrent infections and complications. Guinon, in a discussion of the subject at the Paris Société des Hôp., February 8, stated that he made a practice of putting scarlet-fever children on raw meat, as well as those with slow-healing ulcerations, suppurations and necrosis. The raw meat seemed to exert a remarkably favorable action from the first, especially in the ulcerations that follow the phlegmons of scarlet fever or the necrosis of the palate. The so-called "unsalted diet" is not altogether without salt. A small, carefully measured amount is allowed and its elimination supervised.

Quinin and Arsenic in Syphilis.

Assuming that syphilis is a disease caused by a protozoön, Max Kahane of Vienna (*Wiener klin. therap. Wochft.*), suggests its treatment with the three most effective agents against protozoa: quinin, methylene blue and arsenic acid in suitable doses. The treatment, he suggests, would be appli-

cable only to the primary and secondary forms as active living spirochetes have not yet been demonstrated in tertiary syphilis.

Treatment of Snake Bites.

A correspondent in the *Münch. med. Wochft.* for January 2, writing from Vienna, describes the treatment of snake bites generally practiced in Austria. Elastic constriction is applied to the limb above the bite, and from 20 to 30 c.c. of a solution of chlorinated lime is injected into and around the wound. After it has been injected the ligature is removed and stimulants given, especially alcohol. One part of chlorinated lime is dissolved in twelve parts of water for the mother solution, which is diluted with nine parts water for the injections. The writer states that this treatment has repeatedly established its efficacy, especially for viper bites, although antivenin is always used when procurable.

The Indications for the Use of Digitalis.

Eichorst, in an abstract in *American Medicine*, states that the weakness of the cardiac muscle from any cause, whether due to disease of the cardiac valves, of the myocardium itself, chronic diseases of the respiratory organs, atrophic kidneys, acute infectious diseases or poisons, is the chief indication for the employment of digitalis. He disapproves, however, of the use of digitalis in fibrinous pneumonia and in uremia, except in that it improves the cardiac muscle and increases the excretion of urine. He prefers the powdered digitalis to all other preparations. He regards the cumulative action of digitalis as in a large part imaginary, although anorexia, nausea and vomiting may occasionally occur. In many cases before prescribing digitalis he sends the patient to bed and orders a milk diet, and within three days begins the use of digitalis. If for any reason the pulse rate falls below 60, he suspends the digitalis at once. The delirium which is occasionally noted after the administration of digitalis when given in edematous conditions he regards as due to autointoxication, the result of too rapid absorption of the liquid.

Silver Nitrate for Chronic X-Ray Ulcers.

Mr. W. C. Fuchs, a former x-ray operator, who has suffered for years with chronic ulcers caused by exposure to the x-ray in his business, suggests that we mention a few points in his experience for the benefit of others who may have failed to find relief. All other methods of which he could in any way learn were tried without more than temporary and partial benefit. Dr. H. Roberts, St. Louis, suggested to Mr. Fuchs the use of silver nitrate, in full strength, one drop being applied and allowed to spread over such an area as it would cover. Dr. Roberts had used this on his own hands with success, and Mr. Fuchs found it efficacious. Ulcers which had persisted for six years have healed and others are in process of healing. The skin is becoming normal. Mr. Fuchs does not know of this remedy having been tried by others. We believe that some others have tried it without such pronounced success. It may not be as efficacious for every one.

Treatment of Syphilis by Hypodermic Medication.

The treatment of syphilis by hypodermic medication, according to Campbell Williams, in the *Clinical Journal* (London), may be divided into the subcutaneous, intramuscular and intravenous methods. The advantages claimed for this method of treatment are, first, accuracy and regulation of the dose of mercury administered; second, rapidity of action; third, certainty of absorption; fourth, non-impairment of the digestive functions; fifth, the comparative freedom from the grosser forms of stomatitis; sixth, the mitigation of intestinal disturbances. According to some authorities the use of insoluble mercurial preparations has in some cases been followed within a few moments of the operation by pulmonary infarction. The explanation for this occurrence is probably made on the basis that the injection was intravenous rather than intramuscular, owing to the fact that the point of the needle penetrated within the vessel itself. Williams guards against this occurrence by taking the precaution of either plunging the needle in separately or detaching the syringe from the needle after it has been inserted in order to see whether or not any venous blood escapes through the needle before injecting the insoluble salt.

This procedure is after the experience of Gottheil, of New York.

According to the recorded experience of Lambkin, after the injections of 5,000 doses of metallic mercury suspended in the combined equal volume of lanolin and liquid paraffin no untoward results have followed.

Calomel is sometimes used hypodermically in the treatment of syphilis, although records vary to a great extent as to its usefulness. Some state that the effects of his preparation pass off quickly and that relapses are common after its use. The drawbacks to its employment, as stated by Williams, are the presence of pain after the injection; abscesses which may occur in about 1 per cent. of the cases, regardless of extreme precaution with the injection; swelling and induration of the parts in a day or two after the injection; nodes, varying in size from an olive to that of an orange. These nodes disappear, however, in a few weeks, as a rule, but some persist for six or even twelve months. Whatever may be the preparation used hypodermically, before starting on this method of treatment one should always ascertain whether or not his patient is a "bleeder," as a hemorrhagic diathesis is an absolute contraindication to mercuric injections, either owing to the formation of local hematoma or to the setting up of hemorrhage from the urinary tract. The state of the kidneys must be looked into, and if there is any evidence of the lack of proper elimination unusual care must be exercised in the administration of mercury in whatever form. This is especially the case when the mercurial preparation is introduced, either intramuscularly or intravenously, since the renal apparatus is the principal channel by which the mercury thus introduced is carried off. Consequently Bright's disease contraindicates the use of mercurial injection. The same rule holds good in the treatment of diabetic patients. The presence of tuberculosis is also a contraindication. The mouths of all patients should be carefully watched as soon as the treatment is begun, special care being given to the gums, as mercury frequently is blamed for conditions in the mouth for which it is not responsible.

INTRAMUSCULAR INJECTIONS.

According to this author, the intramuscular injection has supplanted the subcutaneous method. The most convenient location for the administration of the mercury is the gluteal region, using the right and left side alternately. The best location for the puncture should be above the level of the great trochanter, which is supposed to be the region of least sensation. The skin should be properly cleansed by antiseptic measures before the needle is introduced, but it should not be irritated more than necessary. The needle, of course, should be thoroughly sterilized immediately prior to its introduction by being held for a few seconds in the flame of a spirit lamp. After it has cooled it may be plunged into the muscle tissues at right angles until the proper depth has been reached. This depth, of course, varies with the amount of subcutaneous fat present, usually from three-quarters to one inch below the surface of the skin. The precautions above stated should be observed in the injection of the emulsions of the insoluble salts to see that the point of the needle is not engaged in the lumen of a vein. This is not so necessary when the soluble solutions are employed, since they may be injected intravenously without the danger of causing pulmonary intarction. (It might be added that it is absolutely necessary that air be entirely excluded from the barrel of the syringe before introducing the injection.)

After the needle is withdrawn the site of the injection should be gently pressed by the finger for a few moments and light massage given in order to diffuse the fluid in the tissues. The puncture wound is then sealed by means of antiseptic wool saturated in collodion.

The author enumerates quite a number of the preparations of mercury, the most important of which are as follows: The soluble preparations are hydrargyri lactas, hydrargyri succinate and of the insoluble mercury which should be administered in liquid paraffin, oleum olivæ or lanolin and liquid petrolati, the following are the most important: Metallic mercury, hydrargyri oxydum flavum, hydrargyri salicylate, hydrargyri tannate, hydrargyri benzoate, hydrargyri subchloridum. The lactate of mercury which is soluble in about 1 in 7 parts of water is one of the least irritating of all the mercurial

salts. It is recommended that it be instilled as an intramuscular injection in doses of from gr. 1/4 (.015) to gr 1/2 (.03). The author, however, speaks of one of its drawbacks, which is the rapidity with which it is eliminated from the body, consequently the injections must be frequently repeated. On the other hand it is to be recommended strongly on account of its safety and comparatively painless after-effects.

Metallic mercury is administered in the form of gray oil. The formula for making up this combination is as follows:

B. Hydrargyri (metallic)	5ss	2
Unguenti hydrargyri	gr. ii	12
Liquidi petrolati	3i	4

M. Sig.: From 1 to 2 minims at a dose.

Lambkin recommends the following combination:

B. Hydrargyri (metallic)	gr. xv	1
Liquidi petrolati (carbonized 2 p. c.)	3iiss	10

M. Sig.: Ten minims injected hypodermically once a week.

The yellow oil of mercury may be used suspended in oil, but the injections with this preparation are painful and no special advantage can be claimed for it. Gottheil recommends the salicylate of mercury as the best preparation in the treatment of syphilis hypodermically. He recommends the following combination:

R. Hydrargyri salicylatis	gr. xv	1
Liquidi petrolati	3iiss	10

M. Sig.: From 3 to 10 drops injected once a week or once every two weeks.

Gottheil claims that this is a non-irritant preparation and that only slight stiffness is noted on the day following the injection. He also claims that it is as effective as any of the insoluble salts of mercury. The benzoate of mercury is insoluble in cold water and is, therefore, classified as an insoluble salt. It may be given, according to some authorities, in the following combination:

R. Hydrargyri benzoatis		
Sodii chloridi, 3â	gr. v	30
Aqua dest.	3i	30

M. by dissolving with the aid of heat and then filter. Sig.: Ten minims once or twice a week.

In the use of calomel it is said that great pain not infrequently follows the injection. It is regarded by Williams, however, as the remedy *par excellence* for endarteritis and its sequelæ. It is given best by suspending it in sterilized olive oil, combined as follows:

R. Hydrargyri chloridi mitis	gr. v	30
Olei olivæ	3iiss	6

M. Sig.: From 10 to 15 minims introduced hypodermically.

The succinimid of mercury may be given as follows:

R. Hydrarg. succin.	5ss	2
Cocaine hydrochlor.	gr. x	65
Aque dest.	3iiss	45

M. Sig.: Fifteen drops hypodermically twice a week.

Medicolegal

Presumption That Credit Was Given to Husband.

The Supreme Court of Alabama says that the evidence in *Montgomery Street Railway Co. vs. Smith*, a personal injury case brought by the latter party, a married woman, did not show whether the credit for the doctor's bill or medical attendance was given to the husband or to the wife, and in the absence of proof the presumption was that the credit was given to the husband, so that the wife would not be entitled to recover anything therefor.

Hysterical Condition of Witness.

The Supreme Court of Arkansas says that in the case of *Bucker vs. State*, a prosecution of the first named party for seduction, the defendant advanced as grounds for a continuance that the prosecuting witness (the seduced female) "had long been subject to some nervous malady causing hysterics or mental delirium, and had recently suffered an attack from same, and was not, at the time of calling of this case for trial, recovered from such attack; that the importance of the case would necessitate her remaining on the witness-stand an indefinitely long time, and undergo vigorous cross-examination,

which would excite the sympathy of the jurors for her and greatly prejudice the defendant's defense; that in fairness to him he ought not to be compelled to cross-examine the prosecutrix in her present physical condition." But, the court says, this stated no grounds for continuance of the case. The court could not assume in advance that the woman's physical condition, nor the character of the cross-examination of the defendant's counsel, would be such as to excite the sympathy of the jury and to prejudice them against him. If so, the fear of exciting sympathy for the wronged would forbid the courts from bringing to speedy trial persons accused of most any crime. Moreover, the determination of that question fell fairly within the sound discretion of the trial court, and as no abuse of it appeared the Supreme Court would not disturb its exercise.

Some Points from an Extended Litigation for Fees.

The Supreme Court of Missouri, Division No. 2, says, in the case of Logan vs. Field, that suit was instituted before a justice of the peace March 24, 1896, on an account for \$160 for services rendered the defendant by the plaintiff, as a physician. The plaintiff recovered, before the justice, judgment for \$160, the full amount of his claim. The defendant then took the case, by appeal, to the Circuit Court of Jackson County, where, on trial, *de novo* (anew) before the court and jury, the plaintiff again recovered judgment for \$160. From this judgment the defendant appealed to the Kansas City Court of Appeals, where the judgment was reversed and the cause remanded for further trial. Thereafter, on Nov. 17, 1901, the case was again tried in said Circuit Court, and the plaintiff recovered a verdict and judgment for \$50. After unavailing motions for a new trial and an arrest of judgment, the plaintiff appealed from this judgment to the Kansas City Court of Appeals, and thereafter, on his motion, that court transferred the case to this court, where the \$50 judgment is affirmed.

As to the facts in the case: The Supreme Court says that the plaintiff was a practicing physician, making a specialty of diseases of the nose, throat and ear. He had treated the defendant in the year 1890, and his bill for that service was paid. In October, 1892, the defendant applied again for treatment. The trouble he was suffering from in 1890 was different from that of 1892. In the first instance he had an enlargement or thickening of the mucous membrane or lining of the nasal cavity, of which the plaintiff cured him. In 1892 the plaintiff found that he was suffering from inflammation of the turbinate bone, together with inflammation of the frontal sinus. The plaintiff, hoping to relieve the inflammation, and successfully treat the disease without an operation, gave him the treatment sued for, telling him that he could not state whether a cure would be worked, and declining to guaranty that such cure could be effected.

It appeared from the plaintiff's testimony that the defendant was benefited; that the case grew better; that the treatment administered, to relieve the congestion in the canal leading to the sinus was successful, but that, from time to time, the defendant would catch cold and violently blow his nose, thus keeping up the inflammation which tended to close the connection between the sinus and the nasal cavity. The propriety and correctness of the treatment administered by the plaintiff was supported by several physicians, and the defendant's expert testified to the effect that the plaintiff had been pursuing correct practice in endeavoring to work a cure without performing an operation. Nor was there any contention on the part of the defendant that he had been in any way injured by the plaintiff's treatment, though he did testify that he did not think he was benefited thereby.

The result of the litigation is as above stated. The Supreme Court thinks that on the trial last appealed from the case was very fairly presented to the jury by the instructions taken altogether. Among the instructions given on behalf of the plaintiff one was that if the jury found and believed from the evidence that the plaintiff rendered the services sued for to the defendant and at his request, and that no price was fixed or agreed on, then the law implied a promise from the defendant to pay the plaintiff for such services what the same were reasonably worth, if anything; and that this was true with-

out regard to whether the treatment was beneficial to the defendant. Other instructions qualified the words "reasonably worth" by adding "according to the usual charges of the medical profession in this vicinity." Furthermore, the jury was instructed that, if the plaintiff knew that the disease from which the defendant was suffering was in the frontal sinus, and the plaintiff had reasonable cause to believe in the exercise of ordinary care and skill that the same would yield to treatment without an operation, then he had the right to treat the defendant for such trouble until such time as he became reasonably certain it was necessary to perform such operation; and he was entitled to recover for such services what the same were reasonably worth, if anything, without regard to whether the defendant was benefited by such treatment or not.

On the other hand, the jury was instructed, on behalf of the defendant, among other things, that the defendant had the right to expect good faith from the plaintiff, and to rely on the supposed superior knowledge of the plaintiff to discover, determine and advise what course should be pursued in his case. If the treatment sued for was worthless to the defendant, and if the plaintiff then knew, or ought as a man of his profession to have known, of the uncertainty or probable uncertainty of a cure of the defendant from the treatment administered, and the defendant went for and received such treatment, and was encouraged by the plaintiff to receive the same, or because the plaintiff failed to inform him of the uncertainty or probable uncertainty of a cure from such treatment, the verdict should be for the defendant. The plaintiff had no right, even if in the best of faith, to render service of no substantial benefit to the defendant and charge therefor, if he himself had doubt, or as a reasonably prudent and competent physician ought to have had doubt in his mind, of such service being a successful treatment of the defendant's trouble, unless he fully informed the defendant of such doubt, and the defendant, with such information of the uncertainty of the success of the treatment, afterward went for and received the same. If the trouble with which the defendant was suffering, and for which he sought the plaintiff's professional aid, was in the frontal sinus over the defendant's right eye, and an operation was then necessary to relieve the trouble of the defendant, and the plaintiff knew this, or could have known it by the exercise of reasonable skill and effort, then his treatment of the plaintiff was unskillful and improper, and he ought not to recover any amount in this action. The plaintiff could not recover for the service rendered in this case merely because he may have performed such service with the permission or even at the request of the defendant and avoided giving the defendant an express guaranty of a cure.

1. Exophthalmic Goiter.—Dock reports the results of his observations of 32 cases, 29 women and 3 men. The predisposing causes could rarely be discovered. In 12 of the patients previous diseases or nervous shock were noted a short time before the characteristic symptoms. In these cases goiter was the first symptom, but in 12 others a goiter was observed from three to thirty-seven years before the other symptoms came on. The thyroid gland was enlarged in all cases. In 26 a systolic murmur was audible over the thyroid. Tachycar-

dia was present in all but two patients, and in one of these it had been present before the observations began. Observations on the blood pressure showed striking differences. In some the pressure was high, up to 180 mm. Eye symptoms were absent in only three cases. Emaciation was a marked and striking symptom, in two cases amounting to almost or quite half the body weight. Diminution of hydrochloric acid in the stomach was observed in a number of cases, but hypermotility was often associated with this. Two of the patients died; one from complicating disease, the other with acute symptoms. Of the other cases, a number had chronic courses up to fifteen years. Emphasis is laid on the importance of the early diagnosis. Regarding treatment, rest is considered most important, with symptomatic treatment. Experience with some of the organic preparations and x-ray rays are mentioned. Surgical treatment is recommended, with certain limitations.

3. Uses and Abuses of the Free Dispensary.—Kevin believes that one reason for the abuse of the free dispensary lies in the fact that it is to the interest of those connected with the institution to have a large service, also that while dispensaries continue to afford practice, experience, and reputation to young and old doctors and "something for nothing" to the general public, the number of patients will not diminish and physicians will always be applicants for vacancies. He divides those who patronize free dispensaries into four principal classes: 1. Those able but not willing to pay; 2. those who, not knowing a specialist, want to find one without being compelled to pay a specialist's fee; 3. poor, suffering unfortunates, who, either by drink, misfortune, ignorance or poverty, are forced to avail themselves of a dispensary's charity, and 4. hypochondriacs, who find, or try to find, relief from their fancied ailments in the different departments of a hospital dispensary.

5. Bacillus Chlorhydrici.—Under this name Palier describes a microbe which he isolated from the human stomach and cultivated. It is a small, slender, rod-shaped bacillus having slight motility. Its isolation is very difficult. It is Gram negative and aerobic. Spores could not be detected. It is found in hyperchlorhydria and chlorhydria. Palier says that ordinarily this is not a pathogenic microbe, but a physiologic one, aiding digestion. Under adverse circumstances, however, the germ, in conjunction with yeast, may be an important factor in the causation of simple ulcer of the stomach.

- 8 "Bier Treatment by Hyperemia." M. Breuer, Buffalo, N. Y.
- 9 "Chronic and Periodic Vomiting." D. Roberts, Brooklyn.
- 10 "Etiology of Eczema." J. C. McGuire, Washington, D. C.
- 11 "A Few Suggestions in Reference to Consumption." L. Barkan, New York.

7. Problems in Treatment of Pneumonia.—Le Fevre declares that from the very beginning of the attack the physician's efforts should be directed toward controlling the toxemia and its effect. Care should be taken, however, that the treatment does not exhaust the patient. Unless contraindicated, Le Fevre uses saline cathartics freely during the early days of the disease. If the toxemia is exaggerated, the same external methods for causing sweating should be employed as those used in the treatment of acute uremia. He warns against the use of pilocarpin, but advises the use of hot drinks, liquor ammoniacus, and citrate of potassium. As there is generally kidney irritation in this disease, abundance of water is indicated. If there is nausea and vomiting so that the administration of water by the mouth is restricted, enemas of normal saline solution should be substituted. Venesection is indicated in those cases in which the patient seems to be overstimulated by the toxemia. Fresh air is necessary, but cold is not an essential element of the open-air treatment. Le Fevre advises keeping the room at a temperature of 65 F. In cases in which there is pain, opium or one of its derivatives, as a rule, has the best effect. He condemns the tendency to resort to nitroglycerin in cases in which cardiac failure is suspected. He advises two classes of stimulants to be used in cases of loss of vasomotor control: 1. Those acting on the medullary centers—strychnin,

caffeine, atropin and cocaine; 2. those acting directly on the muscular tissue of the arterial system—digitalis, ergot and suprarenal extract. The action on the blood vessels of suprarenal extract of adrenalin chlorid is very rapid and energetic, but its effects are temporary. It should be used in the treatment of sudden vascular collapse. Le Fevre says that no case of pneumonia should be given up as lost until death actually takes place.

8. Bier Treatment by Hyperemia.—Breuer reviews a number of tuberculous cases treated by this method in Bier's clinic during sixteen months. In a long series of not selected cases the wrist showed a cure in 88 per cent., the elbow in 72 per cent., and the foot in 61.5 per cent. Breuer also discusses the application of this treatment to acute inflammatory conditions, such as tonsillitis, otitis media and tuberculous orchitis. Other affections suitable for treatment by hyperemia are septic wounds, fractures, arthritis, lymphangitis, hemarthrosis, neuralgia, neuritis and varicose veins.

9. Chronic and Periodic Vomiting.—Roberts discusses the difficulties that may attend the diagnosis of causation in chronic and periodic vomiting. He says that careful search of the entire body and all its functions may be necessary. He summarizes his deductions as follows:

1. Vomiting of a chronic type, following a gradually developed epigastralgia, from one-half to three hours after the ingestion of food, is attributable to peptic ulcer, gastric or duodenal.
2. Chronic vomiting that occurs from ten to fifteen minutes after food ingestion is attributable to stenosis of the cardia, nervous abnormality, cerebral lesion (occasional rather than chronic), or to protracted acute gastritis.
3. Copious vomiting ten or more hours after food ingestion indicates a muscular insufficiency; frequent repetition indicates a permanent lesion in the nature of a mechanical interference with the exit of food.
4. Vomiting in the night is particularly liable to occur in cholelithiasis, periodic hypersecretion, muscular insufficiency, and nervous abnormality.
5. Vomiting attempts when the stomach is empty indicate a cause other than a gastric lesion, either a reflex cause, a toxemia, a cerebral lesion, or a nervous abnormality.
6. Morning nausea and retching indicate either a beginning of pregnancy, alcoholism, pharyngitis, nephritis, or a nervous abnormality.
7. Periodic vomiting of clear gastric juice of normal or supernormal acidity in any considerable amounts indicates a secretory neurosis or an ulcerative lesion.
8. Vomiting as a sequel of headache, accompanied by severe nausea, but no gastric or abdominal symptoms, characterizes attacks of migraine; in a majority of cases eyestrain is the underlying cause.
9. Attacks of vomiting of sudden onset, with tinnitus, deafness, and vertigo, are attributable to disturbances of pressure in the internal or middle ear.
10. Periodic attacks of vomiting of sudden onset, associated with more or less severe gastric pain and nausea, retraction of the abdomen, obstinate constipation during but not preceding the attack, and freedom from abdominal tenderness, are suggestive of the spinal crises, idiopathic nervous vomiting, and lead poisoning.
11. Periodic attacks of vomiting after abdominal colic and constipation, with localized or general tympany, are suggestive of chronic intestinal stenosis.

10. Etiology of Eczema.—McGuire does not believe that gout, rheumatism and many other of the diseases referred to as factors predisposing to eczema have anything whatever to do either in causing the disease or in influencing it in any way after it has been established, only so far as any "run-down condition" of the general system makes the skin less resistant to irritation. Of course, some persons have skin that is susceptible to inflammation, which varies according to the nature of the irritant. McGuire believes that some time in the near future the term eczema will be limited to that form of cutaneous disease that is caused by some specific parasite acting on a vulnerable skin. He cites one case in which the tendency to the disease appeared to be transmitted to the offspring.

13. **Cholecystectomy.**—Erdmann reports the results obtained in 27 cholecystectomies, complicated or not with other diseases and conditions, and draws attention to the fact that no waiting time for subsidence of infection, etc., was given any of these cases by doing a previous cholecystotomy, nor was local treatment advised. The worst cases of infection and most active invasions did fully as well, if not better, than those of lesser or practically no inflammatory activity.

Twenty-two of the 27 patients were females, the youngest being 27, the eldest 66. Four of the entire number were over 50 years of age. One was a male, aged 27. One patient gave a history of attacks from her tenth year, and one from her twelfth year. Five had histories of previous typhoid, about 20 per cent. of this series. In 1, no history of typhoid was obtainable, and 9 gave a negative history of typhoid. Two deaths occurred in this series, both in non-suppurative, but not in uncomplicated cases. The first patient, a woman, aged 40, a long-suffering patient whose condition was far below par, died from exhaustion in eight days. In this case it was necessary to do a choledochotomy for numerous stones in the common and hepatic ducts. The second patient was a male, aged 27, who vomited black matter after the operation from the moment he was placed on the cart in the operating room. He had 33 stones in a distended and elongated bladder, complicated with a diseased appendix containing 11 concretions. Typhoid bacilli were found in the bile.

Two pregnancies occurred, one five months, miscarriage in twelve hours after the operation. This woman had a temperature of from 99.5 F. to 104 F. for over a week previous to the operation. The other, who was in the seventh week of pregnancy, submitted to an operation for cholelithiasis and appendectomy without aborting. The appendix was removed in 16 out of the 27 cases, in several instances being markedly invaded. Eight patients had gangrene of one or more coats of the bladder. One was doubly perforated, contained two stones and a large abscess well walled off. In 5 cases the common and hepatic or both ducts were opened for stones. Although a history of jaundice was obtained in 12 cases, the jaundice in the remaining 7 is to be explained by the fact that stones were passed through the common duct before the operation in some of them, while in 2 or 3 pressure of exudate and distended bladder could be ascribed as the factor productive of jaundice. Twenty-two operations were for acute inflammatory conditions; all the patients recovered. One operation was for hydrops due to a large stone in the cystic duct, with another free in the bladder; one was done for a primary typhoidal perforation in the beginning of the sixth week of the disease, or rather the first week of convalescence. Erdmann describes his method of operating in detail.

19. **Simultaneous Uterine and Extrauterine Pregnancy.**—Vineberg reports two cases, both ending in recovery. He says that in every case of uterine miscarriage that shows abnormal symptoms, after the uterus has been emptied the probability of an associated extrauterine pregnancy should be considered, and likewise after an operation in a case of extrauterine pregnancy, should there be an undue persistence of uterine bleeding one ought to think of the probability of an associated uterine pregnancy that has been overlooked.

25. **New Gouge for Submucous Operations in Nose.**—Coffin has found his instrument particularly useful in removing cartilaginous and bone thickenings of the septum. The length of the instrument is five inches. (The original article must be referred to for a full description of the instrument.) The advantages claimed for this instrument are: (1) The rapidity with which thickenings under the mucous membrane can be removed; (2) safety; (3) rapid healing, with little or no crusting; (4) ease with which the broad, flat thickenings, which can not be engaged with the saw, can be removed.

42. **Tuberculosis of Cervical Lymphnodes.**—Eisendrath believes that sufficient attention has not been paid heretofore to the primary infection atri in tuberculous cervical lymphadenitis. He makes it a practice to have every patient examined, if possible, before operation by a specialist as to the existence of diseased faucial tonsils, complicated or not by the presence of acenoids. Practical experience has convinced Eisendrath that there are cases of tuberculous cervical lymphadenitis which run a very acute course, so that cessation occurs within two or three weeks after the onset of the disease. He thinks that the majority of these cases are the result of an influenza inflammation of the lymphnodes. He describes in detail the operative technic employed by him in these cases.

44. **Modification of Kronlein's Trigeminal Operation.**—In the method devised by Lexer, the cutaneous incision passes along the upper margin of the zygoma through the skin and temporal fascia. It begins anteriorly at the upper anterior zygomatic angle, close to the posterior margin of the fronto-sphenoidal process, ending posteriorly immediately in front of the temporal artery. It is necessary to cut this. In order to cut the zygoma the posterior angle of the wound is pulled and a needle armed with a chain-saw is passed around the zygomatic process of the temporal bone. The bone is sawed obliquely in a posterior and outward direction. Next a chisel, not too wide—is applied to the upper margin of the zygoma, close to the base of the fronto-sphenoidal process, and the zygoma is severed, with preservation of all soft parts entirely subcutaneously—in a forward and downward direction.

On retracting the mobilized zygoma, inclusive of the margin of the wound downward, the temporal muscle is brought into view. The posterior margin of the muscle is detached bluntly from the bone and forcibly pulled forward by a blunt hook. In case of small facial bones or strongly developed muscles, nicking of the margin of the muscle is advisable. The retraction

tion of the muscle renders the infra-temporal crest accessible. This is located with a blunt instrument (to avoid contact with the finger), and the periosteum is cut exactly on top of the crest. If, by mistake, the insertions of the pterygoid muscles are attacked, the further course of the operation becomes a bloody and difficult one. A blunt hook about 2 cm. in width is applied to the periosteal wound, running at right angles to the infra-temporal crest. Employing the hook as periosteal levator, the periosteum and the pterygoid muscles are detached from the bone. This accomplished, the detached muscles, with the zygoma, are retracted downward and somewhat forward by the hook previously attached to the wound. This exposes at once the infra-temporal fossa (zygomatic fossa), and in its posterior portion the foramen ovale with the third branch. It is not difficult to pull this forward with a small curved hook in order to grasp it by forceps for the purpose of evulsion. The foramen and the vicinity is closely scrutinized for any remaining branches.

If the nerve is grasped close to the foramen ovale, injury of the middle meningeal artery may be avoided. The artery is covered by the condyloid process of the inferior maxilla, and is seen in anatomic specimens in looking downward and backward from the anterior portion of the wound. The incision serves likewise for removal of the second branch, if this becomes necessary. All that is necessary is to place the head in such a position that one can view the field from the anterior margin of the wound in a downward and forward direction. The nerve is located at the entrance of the sphenomaxillary fissure surrounded by loose adipose tissue. From this the nerve is picked up by a hook, separated from the fatty tissue by small sponges and tissue forceps. When absolutely certain that the entire nerve is separated, it is grasped and evulsed.

48. Retroperitoneal Hernia.—McArthur cites a case of hernia in the fossa of Treitz consisting of an incarcerated loop of jejunum of which an accurate diagnosis could not be made before laparotomy, and then only after a most exhaustive search through the abdomen. After a careful study of the history of the case it appeared probable that there existed an acute intestinal obstruction, which might be due either to a mechanical or to an infective-inflammatory cause. In favor of the mechanical nature of the obstruction was the somewhat gradual onset of the obstructive symptoms, without high fever, and with the appearance of blood and mucus in the stools; the blood count, while elevated, not being high enough to be convincing as to the presence of pus. Because of the tenderness over the whole abdomen, the sudden sharp exacerbation of the pains on the second day, and some rise in temperature, attention was directed to the appendix, but without other corroborative signs. Following the eviscerations in the endeavor to find the point of obstruction, almost the entire small intestine was removed from the abdomen before a small loop was found which led to the discovery of the cause of the trouble. The patient made an uneventful recovery.

52. Use of Longitudinal Wire Suture.—The wire used by Harris is aluminum bronze, Nos. 26 and 27, for ordinary purposes. The advantages of this wire over silver wire are its greater tensile strength, consequently a smaller wire can be used, and the fact that it does not kink so readily. The wire can be easily, quickly and certainly sterilized by simply placing it in boiling water with the instruments. In closing a median incision through the abdominal wall, three wire sutures are used, one closing the peritoneum, one in the sheath of the rectus muscle, and one in the skin.

The sutures are introduced in the following manner: A No. 27 aluminum bronze wire is threaded directly in a newly full-curved round needle with a specially constructed eye for carrying wire so that it will not slip in the eye. The needle is made to enter the skin in the midline, 1 to 3 cm. from the angle of the incision, and penetrates obliquely all the tissues down to the peritoneum, where it should appear at the angle of the peritoneal incision. The peritoneum is now taken up with the needle, parallel with and quite near to its edge, first on one side and then on the other, constantly in an advancing manner until the entire length of the incision has been traversed. The grasp of the needle should not be more than a

centimeter in length, and the point of entrance of one grasp should be opposite the point of exit of the last grasp. The suture is then brought obliquely to the surface about the same distance from the cutaneous angle as at its point of entrance.

The second suture, wire, No. 26, enters in the midline, but a little nearer the angle of the incision. It penetrates as far as the sheath of the rectus muscle, where the edges of this fascia are taken up longitudinally in exactly the same manner as has just been described for the peritoneum. No sutures are applied to the recti muscles. At no point in the midline do the recti muscles lie in contact with one another; hence, in closing a median incision, it is unnecessary to suture together the recti muscles with the expectation of obtaining union between them. The dense, thick, conjoined fascia of the linea alba in the upper part of the abdomen or the firm anterior layer of the muscle sheath below Douglas' fold is the all-important layer to be sutured. This is the layer in which the most perfect apposition, edge to edge, should be secured. The third suture is the usual subcutaneous or subcuticular suture. The wire enters and leaves at the angles of the incision, running along in the corium, in and out, in the same manner as has been described for the other two. It does not appear on the skin at any point, except where it enters and leaves. After the wires are introduced they are drawn back and forth until they are perfectly straight and move easily through the tissues.

The wound may now be dressed in any manner one chooses. The method Harris uses is to seal the line of union with silver foil, after the method of Halstead. On this he places a compress of a few layers of plain sterile gauze, over which are folded the ends of the wires, which should be left long. On these is placed another similar compress, followed by the usual dressing of plain sterile gauze and cotton. The wires are usually allowed to remain two weeks. To remove the wires, they should be drawn back and forth gently until loosened in the tissue, then one at a time cut close to the skin and withdrawn. They are easily removed with scarcely any pain. Care should be taken not to break the wires by pulling suddenly before loosening them. In closing the muscle-splitting incision in interval operations for appendicitis, one wire parallels the fibers of the internal oblique and transversalis, entering and leaving the skin some distance from the cutaneous incision, and crossing it almost at right angles. Another wire parallels the fibers of the external oblique, and a third forms the subcuticular suture. The method which Harris uses in operating on inguinal hernia is described in detail.

55. Removable Continuous Sutures.—All laparotomy wounds that are not drained, Davison closes by applying each layer with removable continuous longitudinal silkworm gut sutures. The suture in the fascia of the abdominal wall is fastened by terminal bowknots on the upper surface of the fascia, and the free ends of the suture are allowed to protrude from the wound. The bowknots are untied by traction on the exposed ends, and the suture removed at the completion of the process of healing. The technique of the suture of the wound in a median laparotomy is as follows: All hemorrhage in the wound in the abdominal wall is stopped by sponge pressure, by forceps pressure or by torsion; no catgut whatever is used. The edges of the peritoneum are caught with forceps, and are held up, away from the intestine, by an assistant, and the peritoneum is approximated by a continuous ringhione suture. The suture is lightly shirred to take up all the slack, and the ends are left hanging out of the angles of the wound, temporarily held out of the way by snap forceps. In a median laparotomy the linea alba is the strong layer of the abdominal wall, and if this layer be fastened securely there can be no spreading of the wound. The edges must be accurately approximated. The fat must be cleaned away, so that there shall be no interposition of tissue between the edges of the fascia, as that would weaken the line of union and predispose to ventral hernia. For this suture a perfect strand of silkworm gut, soft and pliable from recent boiling, is selected. A small reverse bowknot is loosely tied 10 or 12 cm. from the end of the strand. The edges of the fascia are caught with forceps and held by an assistant. The suture is introduced in a firm place in the fascia back from the angle of the wound and drawn up to the knot, and the fascia

is approximated by a continuous herring-bone suture. The needle perforations in the fascia are placed about $\frac{1}{2}$ cm. from the edge and 1 cm. apart.

At the last stitch the suture is shirred up tightly, grasped by a smooth (serrations filed off) dissecting forceps at its exit from the fascia, held by an assistant, and another reverse bow-knot tied below the point of the forceps. In tying the knot around the forceps the strand must pass under the forceps, and the loop must pass up from below, or no knot will result. The greatest care must be used not to crush or fray the silkworm gut with the forceps at the knot, for such a defect might cause the strand to break at that point at the time of removal. As the bowknot is intended only to form a body to obstruct the passage of the sutures through the fascia, it should be tied loosely, to make a larger obstruction, and to facilitate its untying at the time of removal. The ends of the tied suture must not be held out of the way by snap forceps, as their weight might untie the knots. The linea alba, being securely fastened, takes all the tension from the other layers, and the unfastened sutures in the other layers do not tend to pull loose.

The skin is closed by the Halstead subcutaneous stitch. If the patient is very fat, an extra running suture can be placed to approximate the fat and to avoid a dead space. If the wound is too long to close with a single silkworm gut strand, it is closed in sections, by repeating each suture. Lateral celiotomies are closed by suturing each layer of fascia with a tied strand of silkworm gut, not allowing muscle or fat to be included in the suture.

59. Multicystic Ovarian Tumor.—Spohn reports this case because of the enormous size of the tumor. The abdomen was so much enlarged that it came almost up to the patient's chin and extended midway between her feet and knees. When she lay on her side on a three-quarter bed the abdomen had to be supported on two chairs. The patient could not reach her navel with her hands by one and one-half feet. When her family wished to move her they rolled the tumor and she went with it. Spohn reduced the size of the tumor gradually by tapping, then opened the abdomen and removed the cyst sac, which weighed forty pounds. The total weight of the tumor was 328 pounds. The patient made a good recovery.

61. Treatment of Malignant Tumors.—Soiland favors the employment of the Roentgen ray in conjunction with surgery in attacking malignant disease. The raying should be begun immediately after the surgeon has removed the growth, or as much of it as possible. A little over a year ago he made an application of powerful x-rays directly into the wound immediately following the extirpation of a large mammary cancer which was accompanied by a great deal of necrotic glandular involvement and pus. The wound healed quickly, without secondary infection, and there has been no sign of recurrence. Two other patients were treated similarly and with equally good results.

62. Unusual Case of Pregnancy.—Spencer relates the case of a woman aged 44, a multipara, who had a very severe hemorrhage at seven and a half months. Four weeks from the date of this hemorrhage there was a slight flow, lasting the usual number of days. Three weeks later there was another flow, which was followed by a third. The latter was accompanied by great bearing-down pain. The os was dilated to admit three fingers, and with but little aid the fetus and placenta

were delivered. The head of the fetus presented a flattened shape; there was neither odor nor blood from the surface of the placenta. The time from the supposed conception until the delivery of the fetus was fully ten months. The interesting feature of this case was the fact that the woman had two normal periods of menstruation, neither of which caused a miscarriage.

63. Rare Case of Hematoma.—On examining a woman who was the victim of delayed labor, Freedman noticed a large globular mass, about the size of a fist, completely occluding the vagina. It was attached to the anterior vaginal wall, and its color and general characteristics pointed to its being a large hematoma. By careful manipulation it was possible to deliver the child, but another child was then discovered in the uterus, and in order to permit of its evacuation Freedman was compelled to incise the hematoma and turn out the clot. The child was delivered successfully with high forceps. All went well and the patient made a perfect recovery.

64. Metastatic Melanosarcoma.—The primary tumor in this case was located in the right anterior occipital convolution and was the size of a walnut. Another tumor was located in the right anterior central convolution near the left Rolandic fissure. Numerous metastatic tumors were found in all parts of the body. Some of the features of interest in the case were the apparent involvement of all the structures in the internal capsule without total and permanent hemiplegia and sensory disturbances; the involvement of the right Rolandic fissure without motor symptoms referable to the left side; the mild subjective symptoms; the non-disturbance of special senses and the very slight mental disturbances; the almost complete amelioration of symptoms at times; the absence of metastases in the lungs, liver, heart, spleen and pancreas.

68. Prodromal Erythema of Variella.—Anthony has observed two cases which he believes were analogous to the prodromal erythema of variola. A child, perfectly healthy, suddenly, without prodromal symptoms or any disorder of the throat or stomach, broke out with an erythematous rash which was not scarlet fever like, but which was something special, because of the watery discharge from the eye. The eruption was accompanied by a few chicken-pox lesions. The variella eruption developed fully and in forty-eight hours the temperature fell to normal. In the case of the second patient the eruption was not accompanied by chicken-pox and the temperature fell to normal in twenty-four hours. Anthony is convinced that these were instances of prodromal eruptions.

69. Resuscitation in Asphyxia Neonatorum.—The method proposed by Himmelsbach was first used by him in March, 1900, since when he has applied it in 20 cases with uniform success. The method consists of a hypodermic injection of 1/1500 grain of sulphate of strychnia and 1/2000 grain of sulphate of atropin.

70. **Tuberculosis of Mesenteric Lymph Glands.**—Sherman cites the case of a girl, 8 years old, who was brought to him with presumably pseudohypertrophic muscular paralysis. Subsequently she developed pain, vomiting, and obstipation, which was complete at first and resisted cathartics, but later yielded to enemata. From that time there was diarrhea, small mucosanguinolent stools being voided two, three or four times a day. Furthermore, a rounded mass, about 8 cm. in diameter, was felt in the abdomen just below the umbilicus. A diagnosis of probable intussusception was made and operation was advised. The operation disclosed a large gland in the mesentery of the ileum and close enough to the spine to press on the mesenteric veins and partially occlude them. The intestine served by these obstructed veins was congested and edematous. As it was impossible to remove the gland without either rupture or injury to the veins, and as, if it was left, it soon must itself break and pour its contents into the peritoneum producing tuberculous peritonitis, the gland, mesentery and intestine, to the extent of 53 cm., were removed and anastomosis was made with a Murphy button. The child had a stormy convalescence, but eventually recovered.

1. Angina Pectoris and an Arterial Reflex of Abdominal Origin.—Russell records his observations regarding an arterial reflex having its origin in the abdomen, the importance of which he thinks has not been fully appreciated. While the active processes of digestion are going on, there is an influx of blood into the splanchnic area. This drainage into the abdominal vessels is balanced in the general circulation by a systemic arterial contraction, evidently a reflex phenomenon originating in the splanchnic system, passing to the vasomotor center in the medulla and then transmitted to the systemic arteries. The changes in the systemic arteries are a reduction in size and an apparent thickening of the arterial wall. The degree of these changes depends on the kind of meal which has been taken. In the big eater and the wine drinker the arterial contraction is associated with a rise of blood pressure and a true increase of

arterial tension. This reflex varies in delicacy in different persons. It exists in all. Russell is convinced that there is a relation between this phenomenon and angina pectoris, and cites several instances in support of his contention. He shows that this hypersensitiveness of the vasomotor center, even in grave angina pectoris, can be reduced, controlled or even removed by dietetic measures, with the result that the anginous seizures are removed or greatly modified. In cases where the arterial spasm is associated with great anatomic change, either in the myocardium or in the coronary vessels, absolute cure can hardly be looked for, says Russell, but in all cases the symptoms of angina pectoris may be much ameliorated by conducting the treatment in accordance with what they indicate. Owing to the varying degree of intensity of the symptoms, Russell suggests that in classifying the cases the simplest distinction might be found in the terms angina pectoris major and angina pectoris minor, the former being confined to those cases in which there is believed to be permanent anatomic change in the heart or its vessels.

2. Food Fever.—Under this term Smith describes an affection consisting of an attack of fever which comes on suddenly, being accompanied by signs, more or less pronounced, of digestive disturbance, lasting in its acute form for several days and lingering on in a modified degree for some weeks. If the attacks occur frequently—once a month or so—their effect on the nutrition of the patient is highly injurious. The subjects of the complaint are usually neurotic children of either sex between the ages of 3 and 12 years. The attack begins with headache, accompanied sometimes by vomiting, sometimes by looseness of the bowels, but always by signs of some kind of digestive upset. The temperature ranges from 101 to 105. The stomach resonance reaches higher than normal, and the edge of the liver can be felt one or two finger-breadths below the costal margin. The urine is high colored, thick and acid. If the patient is left alone, or not treated properly, the temperature remains for some days continuously higher than the normal level. It generally rises a little after taking food and in the evening. At the end of a few days it subsides, either suddenly after a profuse sweat, or gradually, but is often moderately elevated for a week or even longer. To prevent and cut short the attacks, a careful diet is of the utmost importance. Steps must also be taken to prevent any fresh attack of catarrh which would keep up the derangement of the digestive organs. Hygiene is also of importance.

3. Drug Idiosyncrasies and Official Dosage.—Lawthorne says that an official dosage must be recognized as a possible danger to free and responsible personal prescribing, unless its functions and purpose are strictly limited and defined. The personal factor provided by the individual patient should regulate the dosage of any drug which it may be necessary to give him. The careful adaptation of remedies, both qualitative and quantitative, to the wants and idiosyncrasies of the individual patient is an essential part of good practice. Conformity to a stereotyped scale of doses is out of harmony with the liberty and power of scientific prescribing.

5. Hereditary Syphilis and Enteric Fever.—Rollstone cites a case which illustrates how a disease hitherto latent may be roused into fresh activity by an acute illness, though the latter is not etiologically connected with it. His patient, aged 19, had a typical attack of typhoid, the diagnosis being confirmed by all known tests. On the forty-eighth day, when convalescence appeared to be firmly established, the patient complained of pain in the lower jaw, which was accompanied by swelling. Under fifteen-grain doses of potassium iodid, three times daily, the condition speedily disappeared. On careful examination of the patient evidences of hereditary syphilis were found.

8. Measles in the Puerperium.—Campbell's patient, a young primipara, and her brother, a boy 6 years of age, were at a place of public amusement at a time when measles were rather prevalent. The following day both showed signs of having caught cold, but the symptoms disappeared in about thirty-six hours. Three days afterward the woman had a perfectly normal labor and gave birth to a living, healthy child. On the seventh day of her puerperium, her brother showed marked catarrhal symptoms, and on the next day the patient's tem-

perature was almost 100. A typical measles rash appeared, followed by some ear symptoms and a general acial edema. Both patients made perfect recoveries. As soon as the mother became ill the baby was put in charge of a nurse and isolated. Seven days afterward the infant began to be fretful and restless. There was some vomiting, aversion to food and a slight temperature. Within forty-eight hours there was a most typical measles rash, well marked all over the body. The infant recovered. Campbell directs attention to the following points of interest. Though exposed at the same time, the symptoms manifested themselves twenty-four hours sooner in the healthy boy than in the pregnant or parturient woman. The attack was more severe in the former than in the latter, and was least severe in the case of the infant.

9. Adhesive Mediastino Pericarditis.—Bennion regards the pericarditis in this instance as probably of rheumatic origin. At the autopsy it was found that the pericardial sac was quite obliterated and that there were large calcareous deposits in the pericardium all around the base, especially over the inferior vena cava. The heart valves were all competent. The heart muscle was hypertrophied. The patient, a girl aged 13, had measles when a baby, but had never had rheumatic fever or any other illness of importance. She died about four months after the first symptoms were noted.

- 16 Bilharzia Infection of the Vermiform Appendix. J. Burfield.
- 17 Torsion of the Testicle. R. M. Going.

13. Etiology of Oblique Inguinal Hernia.—Murray has been struck by the marked resemblance as regards the shape, general appearance and relationship of the sac in operating for oblique inguinal hernia in infants, older children and adults. From this he infers that the hernias of the old and the young have a common origin, and that in all ordinary inguinal and femoral hernie the sac is preformed and of congenital origin. He suggests that the occurrence or not of hernia depends on two factors—the size of the opening at the internal abdominal ring and the strength of the muscles guarding it. If in the case of patency of the processus vaginalis the opening at the internal abdominal ring be small and the muscles guarding it powerful, then the probabilities of a hernia occurring are slight. If, on the other hand, the opening is large and the inguinal sphincter weak, the probabilities of a hernia occurring are considerable. The frequent occurrence of inguinal hernia in infants would thus be explained.

16. Bilharzia Infection of Appendix.—The patient whose case is reported by Burfield had an attack of appendicitis which eventually left him with a sinus leading to an abscess cavity in close connection with the proximal part of his appendix. This sinus was the means of entry of the bilharzia while the patient was bathing. The bilharzia ova were found in the appendix. There was nothing in the history of this patient to suggest bilharzia infection of the genitourinary tract or of the rectum. The patient never had a diarrhoea and no blood or mucus was ever found in the stools.

17. Torsion of Testicle.—This patient, aged 17 years, appeared to be suffering from an acute orchitis. The symptoms finally demanded operation. On opening the tunica vaginalis, Going found a dark purplish mass in front, which afterward proved to be the globus major of the epididymis, and behind it was the testicle of a fairly normal color and not much enlarged. Going dissected the tunica vaginalis from the surrounding parts, ligated the cord with fine silk close to the external abdominal ring and excised it. A small drainage tube was placed in the lower end of the scrotum through a small incision. The original wound was closed with silkworm-gut sutures and dressed with cyanid gauze. The drainage tube was removed in forty-eight hours. The patient was allowed up on the fourteenth day.

25. Pancreatitis and Biliary Lithiasis.—Quénu and Duval have operated on 4 patients with pancreatitis occurring in the course of a gallstone affection. They have been able to find reports of other cases, bringing the total to 118. All varieties of pancreatitis have been encountered, and Kehr remarked recently that the oftener he operated the more frequently he found lesions in the pancreas. The pancreatitis was chronic in about half the cases on record, and almost always localized in the head of the gland. When the gallstone affection is accompanied by pancreatitis the biliary attack is not typical: there are always certain abnormal details. The location and the nature of the pain are a little different. It may be referred to the stomach or to the region between the sternum and the umbilicus, and the greatest tenderness may be in the center of the epigastrium. The pain may radiate into the back, between the shoulders or toward the left shoulder. Vomiting is more frequent than in simple lithiasis. In one personal case the vomiting was almost uncontrollable. The syndrome is that of pancreatic colic superposed on the gallstone colic. In only 10 cases was a tumor to be palpated, and in some it was supposed to be an invagination. In 2 cases the tumor was palpated under the false ribs on the left. Functional tests of the pancreas are more instructive than the other findings. The urine or the feces, or both, can be examined. In 21 of the cases of acute pancreatitis an operation was undertaken, with 13 deaths. None of the 5 patients with hemorrhagic pancreatitis operated on survived. The cases with suppuration or necrosis terminated fatally in 45 per cent. All but 8 recovered in the 62 patients with chronic pancreatitis treated by operation and ample drainage. The particulars of the total material are summarized and the 4 personal cases are described in detail.

28. Hemorrhage After Torsion of Ovarian Cysts.—The conclusions of this study of hemorrhagic cysts of the ovary are that hemorrhage is frequent in a twisted ovarian cyst, occurring in about half the cases. Treatment should be by prompt laparotomy, even during pregnancy or the puerperium. Pinard's experience has been that premature delivery may be ward off by systematic subcutaneous injection of morphin during the days following the operation. Forty cases of hemorrhage after torsion are collected from the literature, with the history of 2 others from Daniel's personal experience.

29. Radical Treatment of Inguinal Hernia.—Gratschoff writes from Finland to describe a method of closing the inguinal canal which he thinks offers a number of advantages. He uses a piece of steel wire about 13 cm. long, terminating in a small perforated ball at each end. Two small hooks to hold the silk thread are soldered to the wire, which is drawn up into the shape of a bow after it has been introduced into the

inguinal canal. After the hernia has been taken care of, one end of the wire is introduced through the incision and a stout silk thread is fastened to one of the hooks and passed through the end of the wire bow and then around the internal and then the external pillar, and again around them, until enough stitches have been taken. The needle is brought out through the skin and the silk is drawn taut and fastened to the other end of the wire bow. Both wire and sutures are removed by the end of the week. He has thus treated 44 patients with gratifying results.

30. (IX, No. 6.) "La leucoplasie de la vulve, du vagin et de l'utérus. P. Jayle and S. Bender.
 31. "Le sarcome primitif du vagin chez l'adulte. Diagnostic et traitement des tumeurs solides primitives du vagin. M. Rollin.

30. Leucoplasia of Vulva and Vagina.—Jayle and Bender describe the clinical and anatomic findings in 2 cases of vulvo-vaginal leucoplasia, reviewing at the same time 31 cases reported in the literature. The vagina was invaded in only 4 out of the 33 cases. Treatment, they state, should be by ample excision, with a plastic operation if desired. If asepsis is perfect, the scar is soft, supple and not painful. If the patient refuses an operation, the case should be supervised and great care should be taken to ward off all irritation and inflammation from saprophytic infection. The leucoplasia may, and frequently does, lead to cancer. This established fact imposes the greater necessity for total removal of the patch wherever it may be located. In the collected cases the leucoplasia was confined to the vulva in 14 cases, and epitheliomatous degeneration was manifest in 10. Only 2 cases are known of leucoplasia of the vagina only, 5 of leucoplasia of the cervix and 5 of the body of the uterus. The patients were usually in the fifties, but one woman was 30, two were 61 and one was 74. The list includes some cases published in this country, among them Weir's case, published under the heading of chronic pruritus and ichthyosis of the vulva complicated with epithelioma.

31. Sarcoma of the Vagina.—Rollin traces the history, diagnosis and treatment of these growths in the adult. He had occasion to remove a sarcoma the size of a nut from the vagina of a woman of 35. The lump had been noticed for five months, but caused no disturbance. It suddenly began to increase in size, with pain, temperature and swelling. The tumor readily shelled out and microscopic examination showed that it was a spindle-celled sarcoma. Only 18 similar cases are on record, he says. He summarizes them in turn. The patients were generally in the fifties, but one was a girl of 15. The tumor recurred rapidly in this case after extirpation of the primary pedunculated growth, and the patient soon succumbed. In another fatal case the patient was a primipara of 25; in another a ii-para of 30; in another a ii-para of 23; in another a primipara of 38, and in another a married woman, 19 years old, with hemorrhages for seven weeks. A small tumor on the posterior vaginal wall was removed. Fatal recurrence soon followed. The patients were cured by the operation in 6 of the cases, including a iv-para, who noticed the tumor a year before the operation. It was the size of a walnut and was located on the anterior wall of the vagina, but had caused no disturbances. In another instance the tumor in the vagina had caused no disturbance for three years, when it began to grow, ulcerate, bleed and discharge. These symptoms had persisted for three months when the tumor was removed; there has been no further trouble during the ten years since. In Menzel's case the patient, a multipara of 39, presented a large tumor on the anterior wall of the vagina. It had been noticed for three months and was removed without interfering with a seven-months' pregnancy. The growth was a round or spindle-celled sarcoma in each of these cases.

34. Abscess in the Pancreas.—A young butcher was suddenly affected with colic in the upper abdomen for twenty-four hours, which returned a week later. The colic then vanished, but discomfort persisted in the region and he felt ill. The bowels moved only after an enema, but the physician did not notice anything unusual in the stools. Chemical examination, however, revealed that the absorption of fat was very much disturbed. After a test meal of 1,000 gm. milk, 25 gm. butter and 100 gm. white bread, representing 49 gm. of fat (preceded by carmin to mark the test stools), the stools contained 192 gm. of moist and 63 gm. of solid substances, with 29.23 gm. of fat. Only 19.7 per cent. of the fat ingested had been assimilated. A lesion in the pancreas was assumed and the assumption was confirmed by the operation. The patient recovered after evacuation of the abscess found in the pancreas, although the absorption of fat still remained somewhat below normal. When the abdomen is opened in case of a pancreatic lesion the fatty necrosis usually attracts attention. In one of the 3 patients operated on by Brugsch and König this necrosis extended into the omentum and mesentery. It resembles melted fat, but may be absent even in case of pronounced pancreatitis, exudation taking its place. The fluid is sometimes reddish. Still more striking is the exudation into the tissues, the mesentery, colon and omentum being gorged with fluid. The engorgement is most marked in the mesenteric glands or in the glands on the mesocolon, which looked like sausages in one of their cases. Some of the engorged parts of the omentum clumped together to form apparent tumors, which were misleading until their true nature was revealed by the laparotomy. The distribution of the pancreatic effusion is also instructive, as is explained in detail.

35. Affections of the Pancreas in Course of Diabetes.—Hirschfeld has been studying the catarrhal affection of the pancreas which is liable to develop in diabetes, having had occasion to observe 14 such cases. The catarrhal affection of the pancreas induces an acute exacerbation of the diabetic disturbances in the metabolism; it also causes local symptoms and is further distinguished by a tendency to recurrence. He presents evidence to show that in many cases of diabetic coma some acute affection of the pancreas is probably the principal factor. He has observed coma develop in diabetes after overexertion, influenza or an operation, but in other cases, when the coma is supposedly spontaneous and has been preceded for some time by gastrointestinal disturbances, he is convinced that it is in reality due to the extension of the gastrointestinal catarrh to the pancreas. The severer the diabetes the greater the liability that the development of pancreatic colic may usher in diabetic coma, especially when the colic is exceptionally severe. This occurred in 2 out of his 14 cases. The pancreatic colic may be slight and may be confused with gallstone colic or a stomach affection, or with angina pectoris. The characteristic feature is that the glycosuria becomes aggravated during or immediately after the attacks. When other causes for the aggravation can be excluded, it is safe to assume some affection of the pancreas. He thinks that such affections are more common in all forms of diabetes than is generally recognized. The most important sign of an affection of the pancreas in a diabetic is the disturbance in circulation evidenced by the absence of polyuria after copious ingestion of water. He tested 3 of his patients in this way and found that the amount of urine was increased only from 80 to 120 c.c. after ingestion of 400 c.c. of water under conditions in which normal individuals always showed

an increase of from 130 to 300 c.c. The fact that an affection of the pancreas can influence the circulation is demonstrated by the appearance of edema during pancreatic affections. He is convinced that the pancreas is probably involved in every case of diabetes.

38. The Latest Views of Typhoid Infection.—Kutscher reviews the recent evidence which shows that persons may harbor the typhoid bacilli in their bodies for years after an attack of typhoid fever and thus prove a source of contagion for others at any time. The bacilli seem to lurk in the gall bladder after they have vanished from all other points in the body. No means have yet been discovered of annihilating the lurking bacilli. Women seem to predominate among these chronic "bacilli-bearers." Contact infection is assuming more and more importance, and the principles of successful prophylaxis must be the same as for cholera and malaria. The chronic bacilli-bearers should be excluded from such occupations as are liable to spread infection, especially in dairies.

42. Enterogenous Cyanosis.—Since this subject was discussed editorially in THE JOURNAL, July 8, 1905, van den Bergh has encountered 3 more cases and describes them here at length. One patient, a boy of 9, presented sulpho-hemoglobinemia; the others were men of 31 and 51, presenting methemoglobinemia. Three other patients, women suffering from chronic obstipation, exhibited the same tendency to intense cyanosis, especially noticeable in the lips. Their blood also gave the typical spectrum for sulpho-hemoglobin. The child had stenosis of the anus, with a fistula between the urethra and the rectum. The men had suffered for years from chronic enteritis. The attacks resembled cholera in the older man, who had never been in the tropics. The younger man had served for nine years as a soldier in India. In these patients the cyanosis could be produced and banished at will by putting them on a mixed diet or by restricting them exclusively to milk. Chemical tests demonstrated that the formation of nitrites in the intestine and their absorption by the injured walls were the factors causing the transformation of the hemoglobin into methemoglobin. The nitrites could be recovered from the blood—the first time, with one exception, van den Bergh says, that substances formed in the intestinal canal have been positively demonstrated in the blood.

43. Deep Injections of Alcohol for Relief of Neuralgia.—Ostwald's communications on this subject have been recently reviewed in these columns, page 390. He here reports 45 cases of severe chronic facial neuralgia cured by this simple means. He adds a little of some local anesthetic to the alcohol, and slowly injects it for what he calls the "temporary Gas-sectomy." After from five to seven days he repeats the injection, if necessary, but once is usually sufficient. He follows Schlösser's technique closely and has found the procedure effectual, even for treatment of certain cases of spasmodic contracture and for sciatica.

44. Lymphatic Sarcoma Cured by Roentgen Rays.—Cohn has applied Roentgen treatment in 5 cases of malignant lymphoma or lymphatic sarcoma, with a complete cure in 3 cases; another patient is still under treatment and the fifth was dismissed, as the growth was too extensive for the prospect of a cure. To protect the skin as much as possible, he incloses the Crookes' tube in an impermeable cover with a small opening on one side, to which is fitted a short metal tube, likewise impermeable to the rays. They are thus conducted through the tube to the growth, and pressure from the end of the tube on the skin expels the blood. The end of the tube is applied to a different spot on the skin each time, to avoid cumulative action. He has found this tube arrangement useful also to conduct the rays through the mouth to the tonsils or base of the skull in other Roentgen-ray work. He noticed in some of his patients that the spleen became temporarily enlarged while the malignant lymphoma in the neck was being treated.

50. Syphilitic and Hysteric Pseudo-Osteomalacia.—Schlesinger reports the case of a merchant of 41, syphilitic for seven years, who began to develop symptoms suggesting osteomalacia, with painful paresis of the left, then of the right leg and then of the arms. Abrupt abduction of the legs caused severe pain. The tendon reflexes were exaggerated, but there were no objective disturbances on the part of the sensory apparatus of the spine. The symptoms closely resembled those which he observed in osteomalacia in two other men, except that the pains grew worse at night. Antisyphilitic medication soon cleared up the diagnosis and cured the patient. The asymmetry of the phenomena and the skipping of the trunk were important points for differentiation. His experience with another case of pseudo-osteomalacia shows that it may develop on the basis of hysteria alone. Although the symptoms of osteomalacia were typical, yet his attention was attracted by the remarkable variations shown in brief periods of time, in the interference with function and in the pains. The attention of the patient and the influence of suggestion also caused the symptoms to vary abruptly from time to time. Differentiation was completed by the discovery of hysteric stigmata and the lack of any influence from phosphorous.

51. Local Anesthesia.—Braun remarks in the course of this clinical lecture that spinal analgesia is probably destined to supplant mere local anesthesia for operations on the bladder and urethra. But operations on the anus and lower part of the rectum can be admirably performed under local anesthesia alone, with the exception of evacuation of periproctitic abscesses. Complete insensibility can easily be induced by injecting the anesthetic throughout the region in the shape of a cone. Children and adults who behave like children are not good subjects for local anesthesia.

52. Action of Injections of Cholin on Rabbit Blood.—Werner reported last year that injection of radioactivated leithin had the same effect on rabbits as exposure to radium. He now states that injection of cholin, one of the products of the decomposition of leithin, has a similar effect.

53. Mercurial Treatment of Eye Affections.—Schmidt-Rimpler advocates intramuscular injections of mercury, not only for syphilitic ocular affections, but also for certain non-syphilitic ones, such as optic neuritis, suppurative infectious processes, sympathetic ophthalmia and certain forms of detachment of the retina, especially when accompanied by evidences of choroiditis. He relates examples of his experience to illustrate the advantages of mercurial treatment in such cases.

55. Subcutaneous Rupture of Spleen.—Friedheim reports 2 patients cured by prompt splenectomy after the spleen had been ruptured by a kick from a horse or other accident. One was a boy of 4. There had been much internal hemorrhage in both cases, but the blood had quite recuperated by the end of the week in the adult, while four weeks elapsed before the blood returned to normal in the child.

56. To Detect Typhoid Germs in the Blood.—Conradi calls attention to the fact that the bactericidal property of the blood is due in part to its coagulation. By preventing the coagulation the bacteria in the blood are not interfered with, and it is possible to cultivate them. He has found that bile checks coagulation. He draws blood from the ear of the patient directly into some beef gall, to which 10 per cent. of peptone and 10 per cent. of glycerin have been added, and the whole is sterilized with steam. He generally gets from .5 to 2 c.c. of blood and distributes it in test tubes containing the gall mixture in the proportion of 1 to 3. The tubes are then set in the incubator

for from ten to sixteen hours and the contents are then spread on agar plates. He was able to affirm the existence of typhoid in from twenty-six to thirty hours. In 28 cases of typhoid, the typhoid bacilli were grown from the blood in 22 cases and paratyphoid bacilli in the others. In several cases before other tests were positive.

58. Radium Treatment of Trachoma.—Jacoby's experience has demonstrated that radium has an unmistakable therapeutic action in trachoma, but that it is far below the results of ordinary treatment.

60. Intoxication with Beta Eucain.—Kraus relates that a patient requiring internal urethrotomy was injected beforehand with 10 c.c. of a 2 per cent. solution of beta eucain. He was a robust, phlegmatic man of 40. The injection was repeated the next day when he came to have the cut stricture stretched. Almost at once he felt faint and became partly unconscious, with increasing dyspnea, distress and chills, while the breathing grew shallower and shallower. The condition lasted in all for an hour or an hour and a half. The patient was able to eat then, but did not sleep much that night and found that he was somewhat forgetful for a day or so afterward. There was no actual collapse. Treatment was with wine and camphor, faradization of the phrenic nerves in the neck and inhalation of oxygen. Kraus remarks that it is the first time that any mishap has been observed from the use of beta eucain at the clinic (Lewin's Urologic Polyclinic), although it is in daily use there. He refers casually to the 2 cases of intoxication from beta eucain reported by Marciniowski. In one case the patient had a transient syncope, but he says that she was subject to fainting. In the other case, after injection of 1.5 c.c. of a 10 per cent. solution the patient exhibited tonic and clonic spasms, which gradually subsided after fifteen minutes, but were followed by stupor and weakness, the symptoms all passing away by the end of six hours. Dolbeau, he adds, has reported a similar case of intoxication after intravenous injection of beta eucain, and Simon has mentioned transient headache and vomiting in a man whose bladder had been filled with 80 c.c. of a 4 per cent. solution for a Bottini operation.

61. Leucotoxin in Leukemic Blood.—Under the influence of Roentgen exposures and the consequent destruction of leucocytes, a specific leucotoxin is found circulating in the blood which is able to destroy the leucocytes in animals and normal human leucocytes in the test tube. The patient taking Roentgen treatment, whose blood was examined, was a man of 60, with typical lymphatic leukemia. Under the influence of seven exposures the leucocytes dropped in sixteen days from 150,000 to 41,000.

62. Sahli's "Desmod" Test of Chemistry of Stomach.—Sahli's test was given a thorough trial by Kühn, as also by Fiedler, recently, and both found it extremely reliable and a

valuable acquisition to the means of obtaining information in regard to the chemistry of the stomach under natural conditions, without inflicting on the patient the discomfort of the stomach tube. (The Sahli test was described in these columns on page 1819 of vol. xlv.) He has the patient swallow a little iodoform or methylene blue wrapped in a tiny square of fine rubber tissue tied with a piece of raw catgut. If the chemical functions of the stomach are normal, the catgut is soon dissolved in the gastric secretions, and the appearance of the blue in the urine or of the iodine in the urine and saliva testifies to the normal digesting power of the stomach juices. The little bag is swallowed after a meal and the absence of any reaction is proof that the bag was either passed along before the gastric juice could act on it or that the secretory functions of the stomach are defective. Kühn gives the findings in 54 cases of various stomach affections, comparing them with those of other tests. The "desmold" test proved invariably an accurate and delicate criterion of the presence of free hydrochloric acid in the stomach contents. The cancer cases always gave a negative response, as also severe cases of achylia.

63. **Secondary Tumors in the Ovaries.**—Annum distinguishes three varieties of secondary ovarian tumors: the edematous fibroma, the knobby carcinoma and the cystoma with fibro-carcinomatous deposits. He reviews the literature on the subject and warns that the ovary forms a peculiarly favorable soil for the development of secondary tumors in case of cancer of the stomach, breast, intestine, uterus, biliary passages or skin. The route of the metastasis is usually by dissemination of carcinomatous elements in the abdominal cavity, the peritoneum not taking up the scattered elements as readily as the ovary. The lymph and blood routes are also responsible in some cases. The metastatic ovarian cancers frequently form very large growths, entirely filling the abdomen, especially in case of young women. In all cases of neoplasms in the ovary, the stomach should be carefully examined before operating and be tested chemically. During the operation all the abdominal organs should be scrupulously investigated. The primary tumor is frequently so small that it may be easily overlooked. He has encountered 22 cases of metastatic tumors in the ovaries. In the last series of 4, the ovarian tumor was secondary to cancer in the stomach in 3 and to cancer in the colon in the other.

64. **Treatment of Inflamed Uterine Adnexa.**—Steffeek makes a principle of treating inflammatory and swollen conditions in the adnexa with conservative measures at first, rest in bed, superheated air, etc., but if operation becomes necessary he makes a vaginal incision, supplementing it by removal of the adnexa in case of chronic tumefaction. In the severest cases he removes the uterus. He has had a mortality of only 2 in 145 cases treated in this way. Omitting the cases in which a laparotomy was impossible, his mortality was only .7 per cent.

66. **Convulsions Accompanying Hemorrhage in Pancreas.**—The fatal hemorrhage in the pancreas in the case described was not diagnosed during life. The onset was accompanied by convulsions. The patient was a corpulent woman in senile dementia.

72. **Etiology and Treatment of Eclampsia.**—Liepmann has continued his researches on the placenta of eclamptic women, his latest series including 67. He found evidence in all of them of the presence of a toxin which is not encountered in normal placenta. It must be identical with the eclampsia toxin, as the more of the toxin that is found in the placenta the less serious the maternal eclampsia, while when there is little of the toxin in the placenta a larger amount is circulating in the maternal blood. He is convinced that the chorionic villi are concerned in its production, and that the placenta, therefore, is the place of its production. The toxin displays marked affinity for the brain cells, which are paralyzed by its action and which neutralize it. The toxin also acts most injuriously on the kidney parenchyma and next on the liver. The injury to the liver is always secondary to the intoxication. An existing albuminuria is increased by the effect of the toxin. He urges that immediate delivery, therefore, should be the rule for all cases of eclampsia. He gives diagrams comparing the mortality in the expectant and rapid-delivery methods of treatment. The expectant treatment

at certain clinics gave a mortality of 30 per cent., while the mortality at others has been only .8, .8 and 1.8 per cent. since the rule has been followed of delivering all eclamptic parturients without delay. Saline infusion and venesection have sometimes proved useful, and also artificial respiration, according to Sylvester's method, kept up for hours when the patients were very comatose and respiration was shallow. At Bummi's clinic the lowest mortality of all, 1.8 per cent., is reported in 79 cases since April, 1904. None of the women with less than five attacks died. Others were saved who had had ten and thirteen attacks. Experiments are now under way in the effort to produce a serum for the treatment of eclampsia. (See editorial.)

78. **Surgical Treatment of Tabes.**—Schüssler advocates surgical stretching of the nerves after incision as the most rational and effectual of all surgical measures applicable to tabes. He states that tabes is always accompanied by a perineuritic or neuritic process at the periphery, and nerve-stretching is indicated. Its chief effect is in inducing hyperemia, he thinks, and he applies it at the earliest possible moment, insisting that the anatomic findings refer to the periphery the beginning of the lesion in tabes. He has thus treated 44 patients, performing 82 of these nerve-stretching operations on them after an incision. The conditions were most deplorable in a number of the cases, and one patient, much debilitated by mercury and iodid treatment, succumbed to pulmonary embolism.

80. **La yngeal Tuberculosis.**—Stein encountered 170 patients in 474 with tuberculosis of the lungs who presented symptoms of tuberculous involvement of the larynx. The most frequent symptom was hoarseness. About 77 of the patients complained of local pain and 72 of difficulty in swallowing from the first. He was able to improve the condition in 68, so that all pain and difficulty in swallowing passed away, and 8 patients were clinically cured. A number of other patients were materially relieved, although there could be no question of much improvement in their cases. When the diagnosis is assured he institutes general as well as local treatment for the tuberculosis. He commences with prolonged inhalations of menthol twice a day. This frequently proves sufficient to relieve the pain and other symptoms. It is very important to refrain from using the voice; he requires his patients to write all they have to say and not to speak at all. As a last resort he occasionally finds it necessary to use local anesthesia in the form of cocaine or some similar preparation in olive oil.

84. **Tuberculosis of the Conjunctiva.**—Lundsgaard declares that when the tuberculous process in the conjunctiva is not too large for radical extirpation it should be excised into sound tissue. If the process is too large for this, but has not yet in-

vaded the bulbar conjunctiva, then it should be treated with phototherapy. If this is impossible on account of the extension of the process, then tuberculin treatment is justified. The actual cautery, uretting, etc., may be useful adjuvants, but can not be relied on for the whole treatment. The anatomic findings alone are not always sufficient for differentiation; reaction to a test injection of tuberculin is confirmatory of the tuberculous nature of the process, or inoculation of rabbits' eyes may prove decisive. His experience includes 15 cases, which he describes in detail. A number of these patients were treated at Finsen's Light Institute. In several of the cases various methods of treatment had been tried, but without results, until the process was finally arrested and the patients cured by excision into sound tissue. The results of this were always so good that he urges its general adoption as the standard procedure.

87. Treatment of Hypertrophied Prostate.—This article was read by Rousing at the recent International Surgical Congress as the introduction to the discussion on this subject. He preaches that the hypertrophied prostate in itself does not require any treatment; further, that treatment is not required in more than 16 per cent. of the cases in which the enlarged prostate interferes with the free emptying of the bladder. He insists that even when hypertrophied the prostate is a useful and important organ which should not be sacrificed without compelling reasons. Systematic catheterization, he states, should always be given a thorough trial first. It is liable to improve conditions to such an extent as to amount to an actual cure. The question whether to condemn the patient to the catheter perpetually or to remove the necessity for it by an operation is a question that can be decided only by the condition of the bladder muscle. The best way to estimate the condition of the bladder muscle is by the force of the stream of urine when the catheter is introduced. If the bladder is completely paralyzed it is better to cling to the catheter, but if the bladder muscle is still functionally sufficient, vasectomy or prostatectomy should be done, according to the indications. He thinks that vasectomy deserves a better reputation than it now enjoys. He performs vasectomy in every case of soft, diffuse, parenchymatous hypertrophy of the prostate causing trouble. It is contraindicated in case of hard, fibrous hypertrophy and retention from enlargement and protrusion of the median lobe into the bladder. He has cured his patients in 60 per cent. of the 70 cases treated by vasectomy, and materially improved 30 per cent., failing to relieve in only 10 per cent. The mortality is zero, he states; the operation is performed with local anesthetic alone. He is convinced that prostatectomy is done too frequently. Too little attention is paid to the seriousness of this operation, which, he says, puts an end to all sexual life, as well as to the power of procreating. He restricts partial prostatectomy to cases of retention from enlargement of the middle lobe, without pronounced infection of the bladder, and when the patient is resistant enough. He always performs the operation by suprapubic route, which avoids injury of the urethra and rectum and exposes better the field of operation. Total prostatectomy should be reserved for cases in which there is suspicion of cancerous degeneration of the hypertrophied prostate or when there is recurring hemorrhage or abscesses. He prefers Freyer's technique. Suprapubic cystostomy should be reserved for cases in which vasectomy has proved a failure, or when there is retention with threatening infection requiring immediate intervention, or for elderly or much debilitated men, or when the bladder is paralyzed and the systematic, prolonged use of the catheter is difficult or impossible for any reason.

88. Treatment of Throat Affections from Overuse of Speaking Voice.—Myding describes a series of exercises to strengthen the muscles and to teach the patients to use their voices properly, insuring ample respiration by expanding the chest and lowering the diaphragm. He does not use any local treatment except, possibly, some astringent spray, but continues the course of exercises from six to eight weeks, with five or six lessons of half an hour each every week at first and later three or four lessons. The results have been very good and permanent. He thinks that similar training should be given to every one who is planning to take up a life-work which will require much use of the speaking voice, especially teachers. He has recently had ten young women teachers take a prophylactic course of

these exercises with him, and the results have been very encouraging.

92. Sterilization of Laminaria Tents.—Kuhn describes experiences and tests which have demonstrated that laminaria tents can be thoroughly sterilized by heating them to 115 C. for ten minutes.

96. Achylia Gastrica with Pulmonary Phthisis.—Faber describes the anatomic findings in 5 cases of gastric achylia in consumptives. His research on the subject of gastric achylia has demonstrated that the assumption of a purely nervous origin is untenable, as he has found evidences of chronic gastritis in all the patients who presented the symptoms of gastric achylia during life. This applies to the tuberculous as well as to the non-tuberculous cases. The causes of the gastritis may be various.

Books Received

Acknowledgment of all books received will be made in this column and that will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

TWO POSSIBLE CAUSES OF EMACIATION NOT GENERALLY RECOGNIZED.*

RICHARD C. CABOT, M.D.

BOSTON.

Some physicians and many laymen are in the habit of thinking and speaking as if the bulk of the human body could be increased or diminished as simply as we load and unload a vessel: Pour in the cargo and the displacement increases; hoist it out and she rides light on the water. But to feed a patient up or to starve him down is not nearly so simple.

Our state of nutrition depends on the number, the contents and the activities of our body cells; but these cells are not buckets to be filled or emptied at our pleasure. They multiply or atrophy, take up food or reject it, burn fuel or refuse to do so according to their own laws. Without food they can no more do their work than a miner can dig coal or a composer produce sonatas. But no one supposes that you can get good music simply by supplying good food, and it is equally irrational to imagine that good food means good nutrition, independent of the creative and constructive talent of the individual cells. Good food, properly utilized, makes the composers and the cells able to do their work, provided they are otherwise fit for it.

These considerations can be expressed as follows:

SOME FACTORS IN NUTRITION.

- A. *Ingestion of Food (in quantity and quality suited to individual needs).*
- B. *Utilization of Food (digestion, absorption, metabolism, excretion).*
- C. *Cell growth: as influenced by:*

I. AGE: FILLING OUT IN YOUTH; ATROPHY WITH AGE (ARTERIAL?).

II. SEXUAL FACTORS (CASTRATION, PARTURITION, MENOPAUSE).

III. INTERNAL SECRETIONS (ACROMEGALY, PAGET'S DISEASE, MYXEDEMA, GRAVES' DISEASE).

IV. SLEEP AND OTHER FORMS OF REST (RECREATION, CHANGE, ETC.).

V. EXERCISE AND OTHER FORMS OF ACTIVITY (WORK).

VI. HEREDITARY, INDIVIDUAL AND PSYCHIC FACTORS.

The rest of my paper is a discussion of some of these items.

I pass hastily over the factors grouped under A and B. Food requirements exemplify very well that individual factor in hygiene to which I have recently called attention.¹ For example, a corpulent person is not always one who eats more and exercises less than his lean neighbor. *He is one who eats more and exercises less than his individual constitution demands.*

But food in the intestinal canal is still outside the cells. Faults in digestion, absorption, metabolism (e. g., diabetes mellitus) or excretion (nephritis) may render food not merely useless, but actually poisonous to the body cells. Hence, if these activities are themselves out of working order, "good food and plenty of it" may destroy instead of build up the body.

It is, however, to the factors influencing nutrition grouped under C that I wish to direct attention, and my text is this: Cell growth, cell multiplication and cell nutrition are profoundly influenced by age, by sexual influences, by internal secretions, by sleep and exercise, and by a multiplicity of hereditary, individual and psychical factors not yet clearly distinguished.

I. AGE.

In the process of growing up, there is a period when a youth has reached his full height, but has not yet "filled out," as we say. He eats voraciously and seems to "take care of his food" perfectly, but for the thickening up of his body the time has not yet come. A year or two later his cells take on a new type of activity, a new pace, and, without any change in the amount or kind of food taken, his body changes its habit, his nose and jaws grow, and his tailor has to cut his clothes so as to allow for a good deal more beam, though his length over all is the same.

After a time, and without any corresponding change in diet, this furious new production of cells slackens. Growth is complete, or nearly so. The cells again change their type of activity, and now maintain, without notably increasing, their number and their size.

A long period of stability and conservation follows, lasting through the prime of life. Then comes one of the changes in the mode of cell activity, in which I am just now especially interested. I mean the emaciation that develops with increasing age and often without any corresponding change in diet. It is a familiar fact that most elderly persons are thin—thinner than they were in the prime of life. Occasionally this loss of flesh may occur within a relatively short time and may give rise to grave but unfounded apprehension or to a mistake in diagnosis.

On Oct. 1, 1904, I saw, in consultation, a sea captain, aged 49, who had lost 90 pounds of flesh in thirteen months (original weight 265, present weight 175). His health was not bad, his appetite and sleep were excellent, his diet was unchanged, but he and his family physician were not unnaturally alarmed by this loss of weight. To what was it due? I made as thorough an investigation of his organs and functions as I knew how to make and found nothing but a marked beading and lateral motion of the brachial and radial arteries. With some hesitation, therefore, I gave the opinion that he was simply undergoing rather faster than the average the atrophy of old age. The subsequent course of his case has apparently confirmed this opinion. At any

* Read before the San Francisco County Medical Society.

1. "Individual Factors on Hygiene," Boston Medical and Surgical Journal, June 15, 1905.

rate no known disease has developed since that time. His weight continued gradually to fall until it reached 155 about Jan. 1, 1905; since then it has remained practically stationary and he feels as well as ever. No treatment was given.

But we believe that "a man is as old as his arteries." Is it not likely that this emaciation of old age is connected in some way with arteriosclerosis? Since this idea occurred to me I have been noting the recent variations in weight of arteriosclerosis patients seen in my clinic at the Massachusetts General Hospital. Table 1 shows that 85 per cent. of these cases have lost markedly in weight (13 to 60 pounds) within the period in which it is reasonable to suppose that they acquired the arterial degenerations now existing.

TABLE 1.—EMACIATION IN TWENTY CASES OF ARTERIOSCLEROSIS (NOT SELECTED)

Number.	Hospital Number.	Loss of Weight.	Age.
1	3265	60 pounds in 5 years	65 years.
2	4568	60 " 10 "	70 "
3	32117	53 " 20 "	70 "
4	46330	39 " 2 "	60 "
5	46150	36 " 31 "	57 "
6	15883	35 " 10 "	74 "
7	28868	34 5 " 19 "	69 "
8	36507	32 " 20 "	68 "
9	32773	32 " 48 "	72 "
10	45018	24 " 1 "	56 "
11	42936	23 5 " 3 "	58 "
12	19663	21 5 " 16 "	53 "
13	30572	20 5 " 20 "	62 "
14	43604	20 " 2 "	65 "
15	5427	19 5 " 15 "	65 "
16	43654	15 75 " 7 "	62 "
17	32514	13 " 35 "	62 "
18	46031	9 " 7 weeks.	52 "
19	46407	5 " 46 years.	66 "
20	32943	Gained weight (3 pounds) 59 "	

Average loss in 19 cases, 29 5 pounds.

It is, I suppose, the usual experience to find most arteriosclerosis patients thin. It is not merely that emaciation makes it easier to feel the degenerated arteries. The fat arteriosclerotic is, I believe, really less common, although I have not yet collected statistics sufficient to prove this. It may very well be that both the emaciation and the arteriosclerosis are due to a common cause and are not related to each other as cause and effect. All that I am concerned to show is that during the years in which arteriosclerosis is prone to develop the individual is apt to lose weight, usually little by little, sometimes with rather alarming rapidity.

II. SEXUAL FACTORS.

I shall merely allude to certain well-known facts which should make us realize better than we often do how powerful are the mysterious energies of sex in their influence on nutrition and how completely subordinate a rôle is played in certain cases by the more simple and obvious factors, like the amount and kind of food. We are all familiar with the marked changes in build and nutrition which are produced when by castration we turn a bull into an ox, but we do not always stop to notice that this change is relatively independent of any variation in diet. In some animals it has been shown that castration makes no difference in metabolism and that any increase in weight which occurs must be referred to the change in the animal's habits. I know of no direct investigation of this matter in human beings.

The increase in flesh so familiar in women after parturition and at the menopause seems in all probability to be guided by sexual influences. I believe that I have noticed in engaged couples a loss of flesh not accounted for by any variation in diet, sleep or exercise. This is, however, a more doubtful point.

III. INTERNAL SECRETIONS.

Myxedema patients certainly gain weight and exophthalmic goiter patients certainly lose weight without any corresponding observable change in diet, digestion, absorption or excretion. The metabolic processes are influenced profoundly. For example, it has been estimated that exophthalmic goiter patients require from 10 per cent. to 20 per cent. more food to maintain weight than normal individuals.² Otherwise they will emaciate progressively, despite normal appetite, digestion and absorption.

That acromegaly and Paget's disease are due to faulty internal secretions is not by any means proved, but for the purpose of this article no harm is done by so regarding them. What we see in these diseases is that certain tissues suddenly take a start and grow independently of any known changes in the amount or kind of food furnished to the individual. A group of cells takes on a new habit of growth and reproduction and rushes ahead under the guidance of forces wholly outside the pale or the ordinary intake and digestion of food.

IV. SLEEP.

Two years ago my attention was called by the following case to the possibility that emaciation might be due to loss of sleep. A plumber, aged 56, consulted his physician for substernal pain suggesting aneurism, but there were no pressure symptoms and no other physical signs except a well-marked shadow shown up by radioscopic examination and corresponding precisely to that which might be produced by a small aneurism. A remarkable feature about the case, however, was this: In the four months during which he had noticed the pain, he had lost 38 pounds of flesh (183 to 145), although his appetite and digestion had remained excellent throughout. His urine was normal and no other cause for the emaciation could be found. On account of this inexplicable loss of flesh and the absence of any signs of aneurism except the pain and the radiographic shadow, his physician was inclined to think that there was malignant disease in the mediastinum. After seeing this case in consultation and noting that throughout his illness his sleep had been considerably disturbed by pain, I looked up the records of 22 other aneurism cases recently seen in my clinic and in the other departments of the Massachusetts General Hospital and found that all but two of them had lost very markedly in weight and in sleep, though in most cases their appetite was unimpaired.

I have been unable to think of any sufficient reason for the loss of flesh in these aneurism cases unless it is true that loss of sleep (due to pain) prevented the normal processes of tissue repair on which the maintenance of nutrition, in part, depends. This theory is not proof, and will need, I suppose, a great deal of experiment to prove it, but meanwhile I have noticed one or two straws pointing in that direction. First, the haggard look so often seen in the faces of those who have passed a sleepless night. This must be due, I think, to an actual emaciation in the facial tissues. It certainly has all the appearances of local emaciation. Secondly, I have noticed that in some cancer cases, with good appetite and digestion, nutrition did not begin to fail until the pain was sharp enough to prevent a proper allowance of sleep. Thirdly, the loss of weight of some athletes as a crucial contest approaches seems to me perhaps best explained in this way.

TABLE 2.—EMACIATION IN CASES OF THORACIC ANEURISM.

Name.	Ho-spi-tal Reference.	Loss of Weight.	Remarks.
Mahon.	Priv. Rec. B. 2, p. 237.	38 lbs. in 6 weeks.	Appetite and digestion good.
Smith.	594-74	82 lbs. in 16 mos.	
Allerson.	594-42	40 lbs. in 7 years.	Symptoms for 7 years.
McCafferty.	490-424	25 lbs. in 4 months.	
Shaunon.	520-154	20 lbs. in 1 year.	
Nicholas.	595-34	17 lbs. in 2 months.	Appetite good.
Stone.	540-102	35 lbs. in 4 months.	Digestion poor.
Winslow.	553-162	50 lbs. in 10 years.	
Wheelwright.	559-70	25 lbs. in 10 years.	Appetite good, no distress.
Decker.	552-20	30 lbs. in 1 year.	No gastric symptoms.
Bernard.	527-12	25 lbs. in 1 year.	Digestion good, poor appetite.
Eberu.	527-138	21 lbs. in 1 year.	
Jenkins.	531-102	45 lbs. in 6 months.	Appetite and digestion good.
Gilkey.	541-56	20 lbs. in 2 years.	Appetite and digestion good.
Kinsman.	490-46	13 lbs. in 2 months.	Poor appetite.
Peck.	541-60	23 lbs. in 1 year.	No digestive symptoms.
Too-a.	526-96	60 lbs. in 2 years.	Appetite good, slight dyspepsia.
Murray.	526-170	44 lbs. in 1 year.	Appetite good, no dyspepsia.
Cassini.	515-88	20 lbs. in 4 months.	
.....	1724*	8 lbs. in 1 year.	
.....	1736*	35 lbs. in 5 months.	
.....	456*	20 lbs. in 1 year.	
Taylor.	594-96	*Several pounds in a few weeks.	
Winters.	565-42	Great emaciation.	
Johnson.	485-18	*Progressive loss of flesh.	
Forsyth.	858-58	*Very little loss.	
Anabelle.	275-23	No loss of weight.	

*Out-patient department. Average loss in 22 cases, 29 1/4 pounds.

I repeat that I do not consider that I have given proof of the truth of this suggestion that insomnia is a cause of emaciation. I mention it chiefly because I wish to get the opinion of other men on the point and to find out whether any observations besides those quoted have already been recorded.

V. EXERCISE.

On the well-worn topic of the relation of bodily exercise to nutrition I wish merely to emphasize two points:

1. In "building up" a patient by rest and forced feeding it is fat and not muscle that we build. There is no evidence to show that muscle can be increased except (a) by the natural growth of the body, (b) by the adaptation of the mature body to a gradual increase of muscular work, (c) by the extraordinary regenerative processes that occur in convalescence from wasting diseases.³

2. Exercise increases weight when it increases muscle and decreases weight only when the gain in muscle is overbalanced by a greater loss of fat. This explains why some athletes gain and others lose in weight in the earlier part of the football season before any of the other influences which affect them later in the season have become operative (insomnia, "staleness," neurasthenia).

VI. HEREDITARY, INDIVIDUAL AND PSYCHIC FACTORS.

Inextricably mingled in their operation are some of the individual peculiarities (inherited or acquired, physical or psychical) which affect nutrition. There are some persons whose tissues are so repellent that it seems as if no amount of stuffing with food of any kind would fill out their lean shanks. Others seem fatally predestined to obesity after a certain age and, despite a restriction of diet which would keep an ordinary per-

son emaciated, they take on fat at an extraordinary rate.

Trainers are accustomed to say that nervousness and "overtraining" have a controlling influence in the loss of weight which is observable in many athletes when a "big game" gets near. Aspirants for political office and business men in crises lose weight under the conditions of anxiety and excitement which increase as the critical day approaches. Whether these physical influences affect us through their direct influence on metabolism or indirectly through loss of proper sleep (proper in quality as well as in quantity) I do not know. The subject is one of practical importance as well as of scientific interest and deserves careful study.

SUMMARY AND CONCLUSIONS.

1. Loss of weight (gradual or fairly rapid) is often observed as a part of the aging process in persons past middle life.

2. This emaciation is often associated with arteriosclerosis, possibly as a result of it, possibly as the concomitant effect of some third (unknown) factor.

3. The rapid gain in weight often seen in growing children and in the convalescence from wasting diseases is not directly a result of abundant food and may occur even when the food supply is far below normal. The gain must be referred to an extraordinarily rapid cell production due primarily to heightened growth-energy in the cells themselves.

4. That influences connected with the organs of sex may exert a controlling force on nutrition is strongly suggested by the changes in flesh and figure following parturition and the menopause.

5. The importance of internal secretions in the maintenance or perversion of nutrition is exemplified in the emaciation of Graves' disease, the increased weight of the myxedematous, and perhaps in the more local hypertrophies of acromegaly and Paget's disease.

6. The possibly decisive influence of insomnia on weight is suggested by the rapid emaciation sometimes occurring in cases of aneurism when sleep is prevented by pain, though appetite remains excellent.

THE GENERAL CONDITIONS ASSOCIATED WITH INSANITY.

THEIR CONNOTATIONS AND CERTAIN DEDUCTIONS AS TO THEIR SIGNIFICANCE.*

H. A. TOMLINSON, M.D.

Superintendent of St. Peter State Hospital,
ST. PETER, MINN.

The thesis to be defended in this paper is formulated in the following statement: There can not be special change in an organ without general disease in the rest of the organism, and in the study and treatment of the special condition the general involvement and its extent are the most important.

There are two assumptions in this connection which may be made concerning the human organism, based on what is known of its etiology and what has been demonstrated as to the processes of its functional activity. First, that the primary functions are those of vegetation, and that all others are related and in sequence to some form of activity involved in the processes of nutrition; second, that the nervous system is the last in the order of

3. Investigations of the metabolism of convalescents have shown that they gain weight and muscle even if their supply of food is so restricted that a normal person would lose weight on it. When the cells are thus aroused it is impossible to check their magnificent regenerative energy, even by semistarvation.

*Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

development and the most complex in its structure; also, the complexity of the structure and functions of the nervous system has increased in a direct ratio with the demands on the general organism, resulting from changes in and the increasing complexity of its environment. It may be further assumed that the functional cell, wherever found, has a limited potentiality, also a normal plane of response to the incident forces constituted in its environment. This plane of response will, naturally, vary with the individual, and, other things being equal, will depend for the level of its development on the combined capacities of the parents at the time of conception, the competence of the mother during the period of gestation, and the suitability of the individual environment during the period of development. It follows, as the corollary of this statement, that if for any reason the potentiality of the functional cell is abnormally limited, or on account of untoward or disastrous conditions in the environment of the organism is manifested excessively, the limit of capacity in the area or organ will be prematurely reached and the process of degeneration begin. That this is true, arrested and defective development, instability in the nervous system, as well as the different tendencies toward degenerative processes in the vegetative organs abundantly prove. It follows then that in the study of the processes of disease we are concerned first with the capacity of the general organism, then with the evidence of functional incompetence or defective structure in the organ or part involved; and, finally, with the relation of the function of the organ involved to the nutritive or eliminative processes in the general organism. In other words, while the morbid histology in the organ may be special, and the symptomatology resulting from its involvement specific, the pathology is general and the disturbance of the functional activity in the different organs will be in proportion with the intimacy of their relation in function with the organ involved.

During the past twenty-five years many efforts have been made to put the study of insanity on a scientific basis, but so far none of the methods presented have met with universal acceptance. Men doing special work in medicine see in mental aberration a complication or the apparent result of disease conditions which come under their observation and with which they are familiar. Each one has tried to explain the manifestations of insanity from the standpoint of his special field. The gynecologist sees the cause of insanity in women in disease conditions in the pelvis, which may be associated with the insanity, the ophthalmologist in the motor and visual mechanism of the eyes, the general surgeon in the results of cranial traumata or the complications of operative procedure. Among neurologists the effort is being made to explain the perversion of mental activity in terms of disease in the cerebrospinal sensory and motor apparatus, and they see the cause of the insanity in the morphologic change in the structure of the cortical cell. The medical men in hospitals for the insane are still hampered by the inertia of custom and tradition and the persistence of the metaphysical conception of insanity, so that they continue to erect the phases and alternations in the manifestations of mental aberration into entities, to which they apply the terminology of metaphysics. It is unfortunate that the terms used to express facts and describe phenomena do not have the same significance to all who use them, and this laxity of definition is more marked in the terminology of psychiatry than in any other branch of medicine, because, in adapting the language of metaphysics, the nomen-

clature has not been used etymologically. Consequently, terms purely metaphysical in their significance are used to describe conditions or express conceptions based almost solely on the data supplied by the study of development, the formulation of physiologic experiment and the revelations of morbid anatomy and histology. Besides, the manifestations connoted by this metaphysical terminology imply the creation from the phases and alternations in mental aberration of conditions that are *sui generis*, independent of the heredity of the individual affected, his experience or influences in his environment. Whereas, we have only to study the conduct of the individual who is insane to know that the phases of his insanity represent reversions, the alternations, exaggerations and perversions of the normal cycle of mental activity, while the extent of the reversion, the rapidity and extremity of the alternations, will be determined by the degree of loss of mental capacity. Consequently there has been the failure to recognize the inherent inconsistency between the conception suggested by the metaphysical term used to define it and the nature of the data on which it is based. Therefore, the fact that the conditions with which we have to do in the definition of insanity are purely physical is lost sight of or ignored, with the resulting failure to recognize that mental aberration, in its clinical and pathologic aspects, has to do primarily with the potentiality of the nervous organization of the individual, and secondarily, with the perverted or defective processes of metabolism, as they affect the nutrition of the nervous system. In other words, we have to recognize that the degenerative process which makes mental aberration apparent is primarily a general one, affecting the vegetative functions.

The following statistical studies are concerned with all of the patients admitted to the hospital in St. Peter during the past nine years. The object of this method of study was to present all of the facts obtained from the careful examination of the individual patient when admitted, together with a record of the information obtained as to his condition before coming to the hospital.

So far as possible we have avoided arbitrary arrangement and have followed what seems to us to be the natural sequence in the description of the conditions found. The only arbitrary arrangement has been the division of the patients into four classes, representing the different degrees of defect present and the form in which the degeneration is manifested. We have classed as "unstable" all of those individuals, without regard to age, who have become insane and apparently completely recovered. Under the heading "primary degeneration" we have classed all those individuals who have become insane during the period of adolescence and who have not recovered. We class as "consecutive" those who have become insane during the period of adult life as the result of physical disease, mental or physical strain or overwork and who do not recover. Under the head of "senile degeneration" we class all those who become insane after fifty-five years of age and lapse into dementia.

Although this classification is apparently arbitrary, it really is not, except as to the assumption that all who become insane represent some degree of instability or defect.

Under "heredity" are classed those constitutional conditions usually described as diathetic, and which have been found to exist in the parents or near relatives of the patient.

Under "concurrence" is recorded the presence of diathetic conditions in other members of the family in the same generation.

Under "mental state" we designate the manifestations of mental aberration present at the time of admission, and in such terms as seem to us most primary and least liable to misinterpretation.

Under "form of sense perversion" we enumerate the manifestations of perversion in the special senses as we have been able to detect them. The same plan has been followed in the two other subheads of the second table. The statement of the manifestations of intellectual impairment as we have observed them, and the nature of the delusion that they represent.

In the third table is recorded our observation of the physical defects found and the affections of the general nervous system.

The other tables cover the result of physical examination and need no explanation.

These tables, and the methods of study involved in their preparation, have been in use long enough for us to formulate some conclusions as to their value as a means of record and their significance with relation to

proximately 13 per cent., were classed as senile degenerates.

In this study the term heredity is used to indicate any diathetic condition in the parents or grandparents that, on account of its interference with vitality, might result in the production of defective offspring.

One hundred and sixty-six men and 119 women had a neurotic heredity; 269 men and 212 women had a heredity of insanity; 135 men and 76 women had a heredity of alcoholism; 199 men and 170 women had a heredity of phthisis; 59 men and 70 women had a heredity of rheumatism; 72 men and 266 women had a heredity of cancer. Concerning 504 men and 416 women we could not obtain definite information, but what evidence there was, coupled with the history of their mental status, would have classed them relatively among the different subdivisions here given.

In the families of 126 men and 120 women there was a concurrence of insanity; in the families of 89 men and 50 women phthisis; in the families of 7 men and 13

insanity and its manifestations. The result of this method of study has been to determine the relation of the performance of the vegetative functions to mental activity in the insane, and the influence of disease conditions, or impaired functional activity in the body organs, in the production and maintenance of perverted mental activity, as well as the relation between chronic degenerative changes in these organs and similar changes in the brain.

From Jan. 1, 1894, to Jan. 1, 1904, there were admitted for the first time 2,366 persons; 1,129 men and 937 women. Out of this total, 165 men, approximately 12 per cent., and 181 women, approximately 20 per cent., were classed as unstable; 476 men, approximately 33 per cent., and 246 women, approximately 26 per cent., were classed as primary degenerates; 582 men, approximately 41 per cent., and 388 women, approximately 41 per cent., were classed as consecutive degenerates; 206 men, approximately 14 per cent., and 122 women, ap-

proximately 13 per cent., were classed as senile degenerates. It is interesting to note that in both heredity and concurrence, insanity and phthisis occurred with the greatest relative frequency. The association of cancer with the heredity and concurrence of so many of the women is also significant.

We note that 422 men and 266 women were excited; 678 men and 454 women were depressed; 42 men and 50 women were delirious; 77 men and 109 women were stupid; 442 men and 546 women were demented.

All of the patients who were depressed at the time of admission became excited in some degree before they recovered or lapsed into dementia, while all of the patients who were excited at the time of admission became depressed. Besides, those patients who were depressed at the time of admission, who recovered, and were again admitted, were excited in the beginning of the second attack, while those among them who were admitted for

the third time were again depressed. The converse of this alternation occurred in those who were primarily excited. Furthermore, in the small number of cases where it was possible to trace with a fair degree of accuracy the life history of the patient, it was found that there had been alternating periods of exaltation and depression from the period of puberty, increasing in intensity and becoming more prolonged as the individual grew older and the conditions in his environment more exacting. The final outbreak, which made the mental aberration apparent to his family, followed physical deterioration or the operation of some untoward experi-

mentation and cardiac uneasiness arising from gastrointestinal distension, gives rise to ideas of poisoning, as does the fetid breath arising from nasopharyngeal disease, or the disagreeable gustatory sensations associated with a foully coated tongue; while the formications and paresthesiæ associated with neurasthenia and vasomotor disturbance suggest personal defilement or the passage of the electric current. Under the influence of physical states resulting in auto-intoxication, delirium or stupor develops, according to the degree of exhaustion in the nervous system. It was also noted that delirium was most common in those patients that were classed as un-

ence, so that there was sufficient loss of mental capacity to deprive him of self-control.

We describe as demented only those patients in whom the mental reduction has gone so far as to make the loss of mental capacity the most conspicuous element in the insanity.

Ten men and 17 women had olfactory hallucination; 193 men and 160 women visual hallucination; 608 men and 416 women auditory hallucination; 36 men and 38 women gustatory hallucination; 151 men and 48 women tactual hallucination; 115 men and 67 women visceral consciousness; 109 men and 88 women sexual excitement; 78 men and 35 women sexual perversion; while in 491 men and 356 women the form of sense perversion was not apparent.

One hundred and seventy-six men and 70 women had grandiose ideas; 104 men and 194 women depreciatory ideas; 585 men and 566 women persecutory ideas; 612 men and 449 women were confused; 175 men and 170 women were the victims of religiosity.

We do not describe a patient as confused unless the confusion is the predominant element.

Forty men and 42 women had systematized beliefs; in 258 men and 156 women the beliefs were variable; in 663 men and 486 women the beliefs were undefined; in 370 men and 232 women the nature of the delusion was not apparent.

The mental state of the patient was always dependent on the form of sense perversion and the nature of the delusion. That is, those who heard or saw what was pleasing or gratifying were excited; while those who heard, saw or felt what was disagreeable, or that suggested danger or misfortune, were depressed or excited. Sensations from diseased viscera, the embarrassed res-

piration and cardiac uneasiness arising from gastrointestinal distension, gives rise to ideas of poisoning, as does the fetid breath arising from nasopharyngeal disease, or the disagreeable gustatory sensations associated with a foully coated tongue; while the formications and paresthesiæ associated with neurasthenia and vasomotor disturbance suggest personal defilement or the passage of the electric current. Under the influence of physical states resulting in auto-intoxication, delirium or stupor develops, according to the degree of exhaustion in the nervous system. It was also noted that delirium was most common in those patients that were classed as un-

stable, and that the delirium was always preceded by a period of restlessness, insomnia and refusal of food, with the physical evidence of exhaustion.

In 91 men and 150 women there was asymmetry of the head; in 447 men and 594 women there was asymmetry of the face; in 17 men and 84 women there was general deformity.

Totals	519	810	86	650	157	200	57	19	19	9	69	248	16	16	9	69	248	16	16	9	69	248	16	16	9	69	248	16	16		

In 63 men and 27 women the superficial reflexes were exaggerated; in 61 men and 51 women they were diminished; in 361 men and 304 women they were absent. The knee jerk was exaggerated in 480 men and 435

women; in 171 men and 165 women it was diminished; while in 85 men and 60 women it was absent.

In 317 men and 297 women there was local paresis; in 126 men and 59 women general paresis; in 25 men and 12 women there was cerebral paralysis; in 14 men and 8 women bulbar, and in 17 men spinal paralysis; 58 men and 45 women had epilepsy.

In 549 men and 343 women there was a tremor of the tongue; in 178 men and 89 women there was tremor of the facial muscles; in 546 men and 344 women there was tremor of the limbs; in 468 men and 364 women the tremor was with intention; while in 179 men and 141 women it was a rest tremor.

In 320 men and 307 women there was inco-ordination; in 92 men and 36 women clonus was present; in 90 men and 128 women there was some degree of local spasm; while in 6 men and 42 women the spasm was general.

was subinvolution. There were 333 cases of laceration of the cervix and 424 of laceration of the perineum. In 238 cases there was cystocele and in 229 rectocele. There were also a great variety of minor ailments present, as is shown in the tables. Severe pelvic trauma or extreme septic involvement were very uncommon. There were only 79 cases of disease of the ovaries, and none of destructive involvement of the pelvic viscera.

Even where pelvic disorder of some apparent severity was present no complaint was made by the patient, nor was there any evidence from the history accompanying her, that pelvic disease had been complained of or suspected by the family physician.

Treatment, both palliative and operative, however, was always efficient in improving the physical condition of the patient, and, to the extent that a source of irritation was removed, quieting her as well.

With only occasional exceptions the manifestations of disturbance in the sensory and motor parts of the nervous system were what are usually described as functional, because they disappeared as the physical health of the patient was restored. However, the mimesis of focal and system disease in the general nervous system is very close sometimes, and the recovery from paralysis and contracture, after long periods, is apparently marvelous. This is especially true of those motor manifestations which are associated with the different forms of vasomotor disturbance occurring during the progress of chronic degenerative disease in the kidneys.

Among the 937 women, 233 suffered from some form of menstrual disorder; 443 had leucorrhœa, but in the majority of these cases the discharge stopped promptly on the establishment of local cleanliness. In 408 women there was some displacement of the uterus, and in 222 of these cases there were adhesions. In 29 women there

Reference to the tables concerned with the physical conditions present at the time of admission will show that practically all of these patients were suffering from some kind of physical disease, most commonly malnutrition, perversion in the digestive processes and interference with the processes of elimination. The clinical histories in all of the cases included in this study also show that improvement in the mental condition of the patient was dependent on the elimination of these evidences of perverted metabolism, while in those cases where physical examination disclosed the presence of progressive organic degenerative processes, particularly those involving circulation and elimination, the prospect for mental regeneration was equally as hopeless as that for physical restoration; and in those cases where the degree of defect was so marked that dementia was coincident with adolescence, the evidence of arrested development or limited potentiality in other parts of

the organism was equally obvious, as shown in the statistical records concerned with primary degeneration.

In all of the cases there was some degree of mental reduction; and in those cases where excitement was present on admission, it had been preceded by a period of confusion and depression, while in those who were depressed there was antecedent confusion and irritability. The absence of intelligent observation on the part of the relatives of the patient precludes the obtaining of accurate information as to when the mental aberration first manifested itself; but so far as we have been able to determine from repeated and persistent cross-examination, it is safe to say that there had been periods of confusion, suspicion and dread for at least a year before the untoward conduct or overt acts of the individual made the nature of his condition manifest to his friends; because the degree of mental reduction had become so great that, under some special strain, inhibition was no longer possible, and the impulses, centrifugally generated, could no longer be controlled. For obvious reasons, the degree of defect in the nervous organization would determine the extent and permanence of the mental reduction and the order in reversion, as well as the rapidity of the progress of degeneration.

In the progress of degeneration some form of special sense perversion is always apparent. Most frequently auditory, next visual, then tactual and gustatory; and the two latter are most common in those cases where chronic disease involving the digestive tract or the eliminatory organs has been present for some time. The delusions which result grow out of the experiences of the individual which have been disagreeable, mortifying or disastrous, which his confusion and failing mental capacity lead him to associate with his immediate environment; and into consonance with which he interprets the language and conduct of his friends and associates. Introspection and morbid self-consciousness magnify and intensify all self-relations, while the neurasthenia, which results from the effort to overcome the constantly increasing confusion, develops an erethism which registers all impressions in a staccato key, and turns the every-day experiences and trials, heretofore borne with equanimity, into calamities; while the conduct of his friends and the attitude of those about him becomes pregnant with suggestion of accusation, denunciation or threat, and the resulting belief concerns that which has been anticipated and dreaded. Or else, as the result of that eesthesia which follows some forms of intoxication, grandiose ideas develop, which may degenerate into the phantasmagoria of acute exaltation, either material or beatific. Again, a dysesthesia may be present instead, accompanied by painful sensations, dread, fear, agitation or stupor.

The clinical significance of this method of study rests on the assumption that the mind, so called, is not an entity, and can not be treated directly. Also on the fact that the nervous system supplies nothing toward its own nutrition, and is not concerned in the elimination of the waste materials of its own functional activity, but is, on the contrary, dependent on the vegetative organs for its maintenance. It may also be assumed, in consonance with current hypotheses concerning the rôle of auto-intoxication in the production of disease of the nervous system, that the failure in the functional activity of those organs, which have to do with the elimination of waste materials from the general organism, would have a more important bearing on the development and persistence of insanity than would a similar failure in the functional activity of those organs having to do with the preparation of food materials for assimilation. TABLE 5.—GYNECOLOGY.

this connection it should also be recognized that, as it is the principal function of the general nervous system to direct the activities of the rest of the organism, a failure in dirigent function would, of necessity, interfere with the normal activity of the vegetative organs, thus reducing their capacity for work, lowering the general vitality and further decreasing the capacity of the general organism for adaptation to external relations, by involving the retention, not only of the waste products of its activity, but also the generation of toxic substances from the food materials taken into the digestive tract. Finally, we have to consider that, while these conditions affect the majority of individuals in some degree, only a very small percentage of those affected ever become the victims of mental aberration or degenerative brain disease.

Our experience has taught us that, while the extent or degree of the mental disturbance is not necessarily in proportion with the amount and nature of the disease or functional failure in the vegetative organs, in those cases where the degenerative change in the general nervous system is going on, with progressive mental reduction, there is a similar process, developing *pari passu* in the rest of the organism, slowly and unequally in ordinary dementia, rapidly and comparatively uniformly in general paresis, insular sclerosis and hereditary chorea. From these observations it seems obvious that there must be involved in the development of insanity, not only the directly acting cause furnished by the environment of the individual, but also instability or defect in the development of the general nervous system, resulting in a limitation of its potentiality to a varying degree. Furthermore, the groups into which the various manifestations of insanity would naturally fall, would be made up of those individuals in whom there was the same relative degree of defect, and the variations among individuals in the different groups would be the obvious result of difference in experience and environment. In other words, mental activity must necessarily be correlated with all of the organic processes, of which it is the synchronous expression.

Primarily, then, we have to deal with the cerebral potentiality of the individual, as influenced by the conditions in his environment which exhaust this potentiality directly by overtaxation, or indirectly by the influence of impaired vitality in the general organism in further reducing the mental capacity of the individual. Next in importance comes the recognition of the fact that in any given environment the general conditions are practically uniform for all who are included; consequently, if these conditions are harmful to some of those who live under them, there must be some inherent weakness in the individual which fits him to adapt himself to them, so as to conserve his own welfare. When this inability is in the direction of physical activities the result is apparent to every one; but, strangely enough, it has not been recognized as equally obvious that the lack of mental capacity which shows itself in imperfect control and incapacity for persistent effort, are evidences of instability and defect, and therefore the expression of a limited cerebral potentiality. A careful study of the natural history of insanity will show, also, that the mental aberration exists for a long time before it is manifested in the conduct of the individual, and it is a well-known fact that it may be present during his whole life, without materially interfering with his relations with those about him. What is it, then, which makes manifest the insanity? It is the loss of control of the activities that are manifested in conduct! And this loss of control

always follows in the wake of mental reduction; that is, the process of dementia. It is for this reason that those who are not familiar with insanity, from constant association with the insane, can not comprehend the existence of mental aberration unless it is manifested in bizarre conduct, or appreciate mental alienation that is not shown by criminal acts or imbecility. It is, for this reason, too, that degeneration is thought of as a result instead of as a process and dementia as a terminal condition only, instead of as a loss of mental capacity, which may be slight and transient or extreme and progressive. may be slight or transient or extreme and progressive.

Postmortem, in acute insanity, there is nothing distinctive; and the periencephalitis and encephalitis which may be present does not differ from inflammation in the brain and its membranes in those who are not insane. In a few cases, where a large trephine opening in the anterior portion of the skull has enabled us to study the appearance of the membranes and brain surface during life, the distended arachnoid space, flattened convolutions and the white streaks along the vessels did not differ materially from the postmortem appearance in dementia, except that after death the fluid is most commonly gelatinous. The most conspicuous change in the condition and appearance of the coverings of the brain results from the thickening and adhesion of the dura and pia along the median fissure. These adhesions and the fibrous increase interfere with the emptying of the pial veins, and narrow and lumen of the longitudinal sinus. While it is probable that some pial adhesion occurs in almost every one after 35 years of age, these adhesions are at the vertex. It is the progress of this adhesion forward and its extension laterally that is the most constant concomitant of progressive degeneration of the brain in the intellectual sphere. The peculiar arrangement of the lymph channels in the brain also adds to the difficulty, when the circulation is interfered with, so that autointoxication in the brain may be apparent and persistent, when there is no evidence that it is general; and the arrangement of the cortical blood vessels shows how stasis may be present when the general circulation in the brain is not interfered with. The thickening of the pia and the progressive occlusion of its vessels in certain areas explains how easily the nutrition of the cortex may be interfered with permanently, while the resulting lymph and venous stasis mechanically accelerates the progress of atrophy. So that, postmortem, we find flattened convolutions and shallow fissures. These changes are, however, general, not specific, nor peculiar to the insane, although always present in cases of terminal dementia.

In cases of dementia the frontal lobes, anterior to the precentral fissure, are always atrophied, and the extent of the atrophy is in definite proportion with the degree of dementia. This is the only constant macroscopic change in the brain in our experience, but there is usually associated with this shrinkage in the frontal lobes atrophy in the convolutions surrounding the insula, and this atrophy is usually most marked in the convolutions of the operculum. Next in order of frequency is dimpling over the angular gyrus and the superior parietal lobule.

The morbid histology of the brain, in those dying insane, is not only not distinctive, but, as I have shown,¹ similar changes can be produced in the lower animals by starvation and exhaustion. In terminal dementia the

1. "The Pathology of Delirium," American Journal of Insanity, October, 1903.

changes found are similar to those present in senility, only differing in degree and in the number of elements involved.

That which distinguishes the human being from other animals is his ability to appreciate the relation of self to environment, and that which distinguishes human beings from each other, is the extent to which this appreciation is developed, as shown by their conduct. In the light of current knowledge, both physiologic and pathologic, it is obvious that the mind, so called, is not an entity, but, on the contrary, is constituted in the cognition and relation of the impressions which come to the brain through the special senses, and is manifested in the direction of the resulting activities that are concerned with the maintenance of the individual. The recognition and re-relation of the impressions that result from these activities is a more complicated process, and is best described by the term *intellection*, because it has to do with the correlation of recent and pre-existing impressions as they affect the welfare of the individual.

The intellectual horizon of the individual is necessarily limited by his mental capacity, while its extent will be determined by his environment and the nature of his experiences. The same response would not be expected from the individual of limited capacity and no culture as from the keen intellect highly cultivated; nor would the definition of their experiences be equally valuable with relation to their individual welfare. Mental activity is not persistent indefinitely on the same plane any more than is physical activity. That is, there is a cycle consisting of the normal plane of activity, out of which develops a period of exalted activity, to be followed by a more or less gradual fall to the subnormal and the return to the normal. These variations are most apparent and extreme during adolescence, most conspicuous in the unstable, and they may be aberrant in the order of their recurrence. The persistence of the normal plane of activity is also dependent on the physical condition of the individual. Vigor will prolong the exaltation of capacity, while lowered vitality will intensify the depression from the normal plane. Besides, under certain conditions representing strain or exhaustion in the nervous system, a rapid variation in the complements of the cycle may occur, with entire disappearance of the normal plane of activity. Therefore, there is represented in the phases and alternations in the mental activity of the ordinary individual all of those manifestations which, when extreme, are described as the evidences of insanity. That is why confusion is the first manifestation of insanity, to be followed by aberration of relation, which results in special sense perversion, that, in its turn, forms the substantive basis for delusion, and the centrifugally generated impulses by which it is manifested. The emotional manifestations are the obvious sequence and the natural result of the character of the ideas generated, the form of the belief and its definition with relation to the welfare of the individual. However, it is only when the mental reduction has gone so far, and the confusion has become so great, that the individual ceases to be able to recognize and re-relate the impressions coming through the senses from his environment, and properly co-ordinate the activities involved, that he loses control of himself to the extent that his condition becomes apparent to those about him.

All manifestations of motion in the human organism, outside of those automatically generated to meet the demands of the vegetative processes and avoid obvious sources of danger, are in response to the impressions re-

ceived from the conduct of others, and their relation with similar pre-existing impressions, as they have generated and been manifested in our own conduct. Mental activity, then, as ordinarily understood, is manifested in the cognition and relation of the impressions received from our environment of the conduct of others in comparison with our own. The capacity to do this evidences our power of attention, while the ability to persist must necessarily be dependent on the vitality of the general organism. Any failure in this process would mean confusion and inco-ordination from incomplete relation, just as is shown in the motor sphere in locomotor ataxia, chorea or athetosis.

Just as the ordinary processes included in the manifestations of consciousness in the same involve, first, the impression through one of the senses, to be followed by impression through one or more of the others; then the picture formed by the process of relation, the fitting in and combining with analogous pre-existing impressions, the persistence of the picture, its proof by comparison with others, as well as its consonance with like processes in other individuals. So, in the insane, there are like processes going on in the same regular sequence, the result differing because of the perversion of the elements of the cognition, while the aberrant functioning of the brain in the re-representative processes leads to incongruous arrangement and confusion. The sequence is complete in the belief which results from the persistence of the confusion and inco-ordination.

The natural history of insanity shows that mental perversion and aberration are concerned with the first and simplest of these processes, while mental reduction implies loss of capacity to carry out the more complex processes. In other words, mental perversion and aberration are always related with those forms of activity which have for their function the cognition of the purely animal relations; that is, they are concerned with the simplest forms of impression through the senses, while the loss of mental capacity affects the processes of intellection. In the lower types of mental development there is a more or less complete absence of intellection, so that the individual is easily confused by mental effort, sensual hallucination is very common, and is manifested in superstition, taking the form of religiosity, the seeing of ghosts, infliction by witchcraft, the administration of poison, etc.

All of us hear sounds, see objects, perceive odors and tastes which we attribute to something else than their real origin. We are subject to disagreeable tactual sensations and to visceral consciousness. Again, under the influence of fatigue, mental or physical, there is the tendency to lapse into self-consciousness and introspection, with the resulting doubt and suspicion, which is the characteristic of the child and the imbecile. The actions of others, heretofore a matter of indifference, take on a new meaning and significance. And, if the circumstances which determined the morbid introspection were mortifying or distressful, we become furtively suspicious and resentful. However, experience and the evidence of demonstration correct our false impressions. But, in the presence of limited cerebral potentiality, under these same conditions, the transition from temporary to persistent confusion would be easy, and the aberration resulting so marked as to materially interfere with the welfare of the individual and his relations with those about him.

The following conclusions seem to be warranted by the data presented: In dealing with insanity and its manifestations we are concerned with the cerebral po-

tentiality of the individual in considering its nature; with heredity and environment in determining its form and sequence; while the evidence of the involvement of the general organism in the degenerative process must be our guide in anticipating its progress and termination.

DISCUSSION.

DR. G. R. CLARK, Dearborn, Mich., said that, so far as the clinician is concerned, Kraepelin's work has enabled him to classify insanity much better than he could previously. Kraepelin has taken the psychologic view that certain groups of symptoms mean certain things. Take, for example, dementia præcox. The mannerisms are not stereotyped, but the condition includes a liability to impulse simply by the term dementia præcox. It makes no difference what the clinical picture may be. One person may have an impulse to touch the tip on his nose, while another may have an impulse which deters him from doing things, but the underlying cause is the same. Kraepelin calls attention to the fact that the catatonic mannerisms and excitement are two entirely different things from a psychologic point of view. The constitution of the United States declares that every man shall be born free and equal. There never was a bigger lie written, from an embryologic standpoint. Every man that is born has tissue instability, and that we all recognize. Is it not quite possible, aside from assuming instability at the time of his birth, to say that a man is unstable from the very beginning in embryo in certain definite cases? The individual may be brought up with glandular clubfoot. We are only commencing to learn a little about glandular pathology. We know that there is a certain kind of insanity in Addison's disease. We have not seen enough of it, and it has not been studied sufficiently for us to know exactly what the symptomatology is. Dr. Clark thinks that the different tissues in the body are elaborated by distinct secretions. For instance, the thyroid gland has to do with the ideal function of the body. Furthermore, over-exertion of that gland produces exophthalmic goiter. He suggested that the glands of Douglass have something to do with the production of these mental conditions. From the pathologic point of view, some disturbance can be demonstrated in the metabolism, in the perspiration and in the other excretions. We can find indican in the urine and we notice the peculiar odor, and can say it is potassium sulphate or something of that sort, but are we exactly sure that there is not some little volatile product, some animal elimination, present which may have much to do with the symptomatology?

DR. H. G. BRAINARD, Los Angeles, said that insanity is based on two general conditions: First, that of nervous instability, and, second, that of stress. The nervous stability, of course, may be interfered with by any condition, perhaps by heredity, from the embryo, as has been suggested, and, again, by things which come later in life, as acute or chronic diseases, and, still further, by the stress of every-day life and the disturbances of metabolism. One person with a well-balanced nervous system may stand all sorts of stress without any insanity, but the man who starts out in life with an unstable nervous system is easily upset by any disturbance in metabolism.

DR. J. H. McBRIDE, Pasadena, Cal., said that it is fortunate that Thomas Jefferson was not an embryologist. If he had been, he would not have written the Declaration of Independence. He did not mean that all men were equal mentally or morally, but that they were, or should be, equal before the law. Medical literature is much indebted, in its terms and even in its conceptions, to Herbert Spencer, who, among other things, showed how degeneration works in organic beings, how it unfolds, step by step, the work of organization. As our mentality has been an evolution, as its physical basis has been built up from the simple to the complex, in ever-increasing intricacy of structure, so insanity, being a degeneration, begins at the highest and last evolved and unfolds in reverse order the work of evolution. No classification of insanity is satisfactory. Those of Dercum and Kraepelin are perhaps the best.

DR. H. A. TOMLINSON, St. Peter, Minn., said that unfortu-

nately he had to pass over that part of his paper which gave the reason for the classification used, so that the basis for this method of classification is not apparent. The objection to the classification that is so popular at present in this country is that metaphysical terms are used to describe physical conditions; and not only that, but the phases and alternations in mental activity which, in their ordinary manifestations, are normal, are grouped together and classed as entities. Any one who has lived with the insane and watched them closely knows that every form of mental disturbance included in the classification referred to may be present during the course of the insanity of any given individual. For example, take the terms excitement and depression: Properly used they describe states of feeling, not forms of disease, and they are dependent on some antecedent impression, either from the environment of the individual or centrifugally generated. Excitement or depression, however, can not differ in kind; they can only vary in degree, and in all cases of insanity excitement and depression are the most common manifestations of mental disturbance. Back of the excitement or depression are the confusion and sense perversion that gave rise to them. In Dr. Tomlinson's experience the greatest harm in the metaphysical classification of insanity and the concentration of attention on the manifestations of mental aberration, is its effect on the physician unfamiliar with insanity. He bases his diagnosis on nothing, and in his treatment chases the will-o'-the-wisp of mental entity. Again, there is a method of classification that would assign certain forms of mental disturbance as the result of certain forms of physical disease, such as cardiac, renal, septic, etc., losing sight of the fact that among the vast number of people who suffer from these disease conditions only a very few show any evidence of mental disturbance. People become insane, why? Because of defective nervous organization, and not because of the cardiac or renal disease. The physical disease simply upsets the unstable nervous organization. It is the same with degeneration. This condition represents the antitheses to development, and while it may vary in degree, or in the rate of its progress, it does not differ in kind. Besides, no matter what may have been the cause of the process of degeneration, the histologic changes that result will be the same kind, differing only in degree. Dr. Tomlinson has been able to demonstrate that the histologic changes found postmortem in acute insanity manifested in depression or excitement, and in the brains of those who were not insane, but died in the delirium of typhoid fever or septicæmia, were not only the same in kind, but also in degree. He has also produced the same conditions in animals by bringing about death from starvation and exhaustion. It is for these reasons that he advocates a classification of mental aberration that shall be based on the cerebral potentiality of the individual as shown by the degree of instability or defect present; and a method of treatment based on the clinical study of the physical conditions present, and not on the form or nature of the mental disturbance.

DR. WILLIAM HOUSE, Portland, Ore., called attention to a statement made by Dr. Tomlinson in the discussion that there is no such thing as insanity due to heart failure. Dr. House is quite willing to agree that there is no specific form of insanity limited to disease of the heart, and yet he insists that disease of the heart, of the kidneys or of almost any other organ, unquestionably may act as a cause of true insanity. It is unfortunate that this is not more frequently insisted on, for, after all, results must be achieved not so much by therapeutic attention to the purely psychologic details as to the physical causes underlying them, and to the inability to grasp this relationship we owe many of our failures to achieve good results in the treatment of the insane.

Reproduction of Bony Structures by Mammals. At a meeting of the London Zoological Society, according to *Nature*, Mr. Oldfield Thomas exhibited a specimen showing a partial regeneration of the caudal vertebra in a dormouse. Other specimens had been obtained showing similar regeneration and proving apparently that the partial reproduction of bony structures not hitherto observed in mammals, was possible in the dormouse (*Graphiurus*).

AUTOLYSIS.*

P. A. LEVENE, M.D.

NEW YORK.

TISSUE DISINTEGRATION.

The most constant property of living matter is disintegration. This precedes every other manifestation of life of the simplest and of the most complex animated organism. The development of a fertilized egg begins with disintegration of its original structure. When the egg is placed under conditions which make the initial disintegration impossible, life remains suspended. Disintegration also is the most lasting property of living matter, for when all other functions are extinct this property is still in evidence, and, if conditions are favorable, the disintegration proceeds until all that could remain of organization or of structure disappears, giving place to a mixture of organic and inorganic substances.

Disintegration of organic matter present in the cells and tissues is also the primary source of that form of vital energy which controls most functions of a living organism. Contraction of muscle, secretion of glands, peristaltic movements of the gastrointestinal tract, growth and reproduction of an organism, are possible only so long as the breaking-down process continues. This has been realized by physiologists at all times. However, the mechanism and the exact nature of the chemical reactions associated with animal functions has never been very clear, and even to-day the question remains a topic of considerable controversy.

Lavoisier was the first to emphasize strongly the similarity between the chemical reactions in the living organism and those in the process of combustion. Ever since that time physiologists have adopted the term combustion in order to signify the chemical reactions in the organism which result in the production of animal energy. Physiologists speak of burning or non-burning in the human or in the animal body of proteid, fat or sugar, of burning of the body tissues and of body cells. Indeed, the ultimate products of the reactions in the body are very similar to those on the burning of carbonaceous material. Carbon dioxide, water and heat are formed in both instances. However, there has always existed an utter lack of information regarding the agents causing the powerful oxidation of organic material in the animal body. The simplest way out of the difficulty seemed to ascribe the power of combustion to a peculiar property of the living cell.

In recent years there has accumulated a great number of observations tending to show that various functions previously regarded as the result of life, as the result of cell assimilation and disintegration by the animal tissues, are actually occasioned by substances which can be isolated from the living cell. An instance illustrative of this statement is found in the work on alcoholic fermentation. Formation of alcohol from grape sugar by the yeast cell was regarded as a chemical reaction brought about by the activity of the cell. Alcohol thus was considered a catabolic product of cell metabolism. Mue, Manassein, and more convincingly Buchner, have demonstrated that from the cell can be obtained one substance which is capable of accomplishing the alcoholic fermentation of sugar in the same manner as the living cell. This startling discovery marks a radical change in our conception of the process of life.

For centuries it was thought that the activity of a complex organism was needed to manufacture spirits out of grape sugar, and the foregoing work demonstrated that the cell may be crushed, its life may be extinct, and one substance soluble in water may be extracted which possesses the power to accomplish the work of the entire cell. True, the substance is of a very subtle nature and needs to be handled with great care. It does not resist the action of heat and other strong chemical and physical agents, but while intact it is capable of inducing chemical reactions into which it apparently does not enter itself, and thus is capable of performing work out of proportion to its own mass. Substances endowed with this power are designated enzymes or ferments. The work of Buchner caused a very intense interest to be directed toward the older and unsystematic work on the enzymotic processes in the cells of the simple and complex organisms.

As already stated, the source of all vital and animal energy lies in tissue disintegration, and the prevailing conception has been that the disintegration was brought about by the power of the living cell to burn its own components. It is the great merit of Salkowski to have shown that a cell or tissue in which all visible signs of life have disappeared still retains the power of self-dissolution, of self-disintegration, of autolysis. True, the phenomenon had not escaped the observation of earlier workers, and in 1871 Hoppe-Seyler wrote:¹ "All organs suffering death within the organism, in the absence of oxygen, undergo softening and dissolution in a manner resembling that of putrefaction. In the course of that process, albuminous matter gives rise to leucin and tyrosin, fat to free acids and soaps. This maceration, identical with the pathologic conception of softening, is accomplished without giving rise to ill odor, and is a process similar to the one resulting from the action of water, acids and digestive enzymes." In 1874 the French chemist, Schutzenberger² observed similar changes in yeast which had been allowed to remain for from 12 to 15 hours in water suspension at a temperature of from 35 to 40 C.

However, before going into the details of the chemical analysis, attention has been called to the structural, morphologic changes which cells and tissues undergo when they are placed in conditions which do not permit continuation of life. It is well known that animal tissues and organs are readily invaded by micro-organisms, causing putrefaction. The application of the recent methods of aseptic surgery allows the removal of organs from the animal body and the preserving of them free from all contamination with micro-organisms. Hauser,³ as well as Rindfleisch and Meissner previous to him, succeeded in preserving tissues for months and years free from infection with any bacteria. In organs kept in absolutely sterile condition Hauser observed general softening, and microscopically he noted the destruction of the most typical structural part of the cell, of the nuclear material, and decay of the mass of the cell, made apparent by the development of changes which are designated by pathologists as fatty degeneration.

Thus the term softening is not merely a figure of speech, but applies to an actual occurrence. This is made evident particularly through the work of Schutz-

enberger and the workers who followed him. Normal fresh organs on extraction with boiling hot water give off only a small fraction of their constituents, while those that have undergone the process of softening allow a very considerable part of their substance to pass into the boiling water. Thus, fresh yeast on boiling with hot water leaves a residue consisting of from 20 to 21 per cent. of its original weight, while the residue of yeast kept in water for from 12 to 15 hours does not exceed 13 per cent. However, in the experiment of Hauser, although the tissues were placed in conditions unfavorable for continuation of life, death set in slowly, and the possibility is not excluded that the softening was accomplished by the vital force not yet completely extinct. Also in the experiments of Schutzenberger this possibility was not excluded; besides, yeast always contains bacteria and it is difficult to separate the part of the changes wrought by the action of micro-organisms from that induced by the surviving yeast cell.

Salkowski was the first to preserve the material employed in his experiments under conditions which checked all other functions, leaving unassailed only the one of dissolution, in conditions in which bacterial growth was impossible. This was achieved by the use of chloroform water instead of the pure. Salkowski repeated the experiments of Schutzenberger on yeast and arrived at the same conclusions as the first observer. He extended the work to animal tissues, using the liver and muscle. The results are best seen in the following table:

From 1,000 grams of liver were extracted by hot water	Autolysed organ.	Control.	Difference.
Organic substance	45.97 gms.	33.73 gms.	12.24 gms.
Ash	7.95 gms.	7.21 gms.	0.74 gms.
Phosphoric acid	1.957 gms.	1.359 gms.	0.598 gms.
Nitrogen in form of nitrogenous substances	6.239 gms.	3.152 gms.	3.087 gms.

In the main experiment the finely-divided organ was mixed with three times its weight of chloroform water and allowed to stand and at given intervals analyzed. In the control experiment the organ was heated and then further treated in the same manner as in the principal experiment. The table clearly shows that, on standing, substances soluble in hot water have developed in the organ. Very similar changes occur in tissues subjected to the influence of digestive enzymes, either in the digestive tract or outside of the body. Because of this analogy Salkowski introduced the term "self-digestion" in order to designate the process occurring in tissues allowed to stand under antiseptic conditions. For reasons which will be made clear in the course of the discussion, the process later was named by Hofmeister "autolysis."

Thus the researches of Salkowski have established the fact that tissues, placed in conditions which do not allow contamination with live matter, undergo changes resembling those occurring during process of digestion; but they offered no information regarding the rôle played by the process in the economy of the organism, in those transformations of matter which create and maintain life. It was still undecided whether or not the capacity of self-digestion was a universal property of all tissues. The probability was not excluded that the autolysis of an organ was brought about by the action of enzymes absorbed from the gastrointestinal tract and transported to the various organs. The researches following those of Salkowski endeavored to give an answer to those questions. The solution of the first problem was comparatively an easy matter. It required only to repeat his experiments on various other organs. This was accomplished most successfully by the efforts of Hedlin and Rowland.⁵ It may be noted here that the last two inves-

tigators employed in their experiments not the entire tissue nor the tissue extracts, but the plasma of the organs. In this manner they made certain that no cellular elements were playing any part in their experiments and that the reactions were caused by a soluble substance present in the plasma. Previously Schwiening,⁶ a pupil of Salkowski, had established the same fact by employing filtered tissue extracts. The work was further extended by Martin Jacoby⁷ and by Stookey and myself.⁷ As a result of all the work it may be regarded as established that the power of self-digestion is shared equally by all organs. The solution of the second problem, namely, of the origin of the autolysing power, required more ingenuity and perhaps more work. Attempts were made to obtain the desired information in various ways. If the digesting power present in the organs is due to a substance derived from the pancreas, the autolysis of organs must be influenced by the same factors in the same manner as pancreatic digestion; further, if that assumption be correct, one would expect to find among the products of autolysis those substances which arise on tryptic digestion.

Matthes sought to solve the question by removing the pancreas from dogs and studying the self-digesting power of their organs. The chemical composition of animal organs is very complex, but the pancreatic gland is capable of disintegrating all the principal tissue constituents, although it resorts to a different mechanism, perhaps to a different substance, for the digestion of the individual substance. The principal components of tissues are albuminous material, carbohydrates and fats. In the course of self-digestion all these components are disintegrated, and it is a matter of convenience to discuss separately the change which each of the components undergoes in the course of autolysis. Of all enzymatic processes that resulting from the breaking up of the proteid molecule has been studied in the greatest detail. For this reason the study of the proteolytic action of organs was employed for the investigations into the origin of the autolytic power of tissues.

Two proteolytic enzymes of distinct individuality have always been known—pepsin, elaborated by the glandular apparatus of the stomach, and trypsin, formed in the pancreatic gland. The principal point of distinction between the two substances is that one requires for its action the presence of acid, while the other is most active in the presence of alkali. Further, it has generally been accepted that pepsin is incapable of producing the same degree of cleavage as trypsin. The formation of crystalline products of amino-acids has been noted only on tryptic digestion. Most typical for the cleavage by the ferment of the pancreatic gland is considered the appearance of a substance giving a peculiar color test with bromin, named tryptophan. In the course of digestion by either of the two enzymes, albumoses and peptones are formed.

Biondi, a student of Salkowski, has noted that the proteolytic action of the liver is facilitated by the presence of acids. This difference in intensity of digestion under the two different conditions is made very conspicuous by the following table:

Out of 1,000 gms. of liver passed into solution.	Experiment 1. With 0.25 HCl.	Experiment 2. Without HCl.
Organic substances	100.10 gms.	59.6 gms.
Ash	26.60 gms.	11.12 gms.
N. in nitrogenous substances	11.76 gms.	7. gms.
Albumose	Trace.	Trace.
Pepton	None.	None.

The conditions influencing the intensity of autolysis were studied in greater detail by Hedin and Rowland,⁴ whose investigations were made on tissue plasma obtained by Buchner's method. It was established by these writers that the self-digestion of the majority of organs is facilitated by the presence of 0.25 per cent. of acetic acid and is depressed by the presence of alkalies, by calcium carbonate and magnesium oxid. The only deviation from this, according to Hedin and Rowland, is in the muscle tissue, where the intensity of digestion is not affected by the presence of alkali or acid. On the other hand, cardiac muscle is subject to the general rule of autolysis. The autolysis of nerve tissue, and of the testes also, is facilitated by the presence of acid, as was demonstrated by Stookey and myself.

These observations are important, for the reason that they make very improbable the supposition that self-digestion of tissues is caused by trypsin deposited in the organs by the blood supply. On the other hand, Salkowski, in his early work on autolysis, has noted the appearance of leucin and tyrosin, and in this respect the proteolytic action of animal tissues resembles tryptic digestion. Contradictory to this seemed the observations of Biondi.⁸ This author could not detect tryptophan in the experiments in which the absence of bacterial growth was made certain. Another peculiarity of the autolytic cleavage noted by Biondi is the comparatively insignificant formation of albumose and of peptone. Jacoby also, in his very exhaustive study on autolysis, invites special attention to the foregoing difference between tryptic and autolytic digestion. On the other hand, Jacoby demonstrated tryptophan among the products of self-digestion of tissues. Thus the chemical process of autolysis bears some resemblance to either form of digestion, peptic and tryptic, and yet is different from each of them. This alone makes it very probable that animal tissues do not borrow their power of disintegration from either gastric or pancreatic gland, and that self-digestion is one of the general properties of living or, rather, surviving organs.

Additional evidence in support of these assumptions was brought forward by Matthes.⁹ It is well known that urine of normal individuals contains a proteolytic enzyme resembling pepsin. Matthes demonstrated that after the removal of the stomach of dogs the enzyme ceases to be eliminated by the urine. It was natural on the basis of this experiment to view the stomach as the source of the urinary pepsin. The same method of investigation was applied by Matthes to the study of the origin of the self-digesting power of organs and tissues. Dogs were deprived of their pancreas and allowed to recover from the operation. The organs were then examined for their proteolytic power. No difference could be detected between the organs of the normal and those of the operated animal. Thus, all evidence seemed unanimously to support the view that self-digestion is a constant property of surviving tissue.

However, for the interpretation of the rôle of this function in the economy of the living organisms, it still remained to be established whether or not the process of self-disintegration takes place also in life. Jacoby⁶ was the first to give experimental trial of the question. For this purpose he performed on dogs the following operations: The hepatic artery and the portal vein were ligated and, after several hours, the liver was extirpated and analyzed for amino-acids. Leucin and tyrosin were found to be present. Further, he

obtained the same results on ligating a part of the liver. These substances were also obtained by Jacoby from organs extirpated aseptically and kept under conditions in which contamination was impossible. It may be remarked that all these methods are open to some objections. More convincing seems to me the analysis of the developing organism. It has been known for some time, through the work of Schulze and his pupils, that in the course of germination and growth of plants, substances appear which arise also on proteolytic digestion of the seeds. I have made a similar observation on the developing egg of fish and of fowl.¹⁰ In the course of development of the egg one can notice the breakdown of the albuminous matter and the appearance of products of the nature of nitrogenous acids.

So, at the present time, there is sufficient evidence for the assumption that disintegration or self-digestion is a constant occurrence in living as well as in surviving tissues. However, there is still a lack of information regarding the rôle of this function in the mechanism of life. In the animal tissue, organ or cell one has to distinguish two different parts, one representing the organized mechanism controlling its function, the other consisting of various organic substances stored up or deposited in the organs, as a supply of fuel material. Blood plasma and lymph, which envelop every part of the organ, are not integral parts of its tissue. They only furnish the material which the organ may or may not use. White of an egg and the greatest part of its yolk are only building material for the developing organism.

In physiology there are two views regarding the production of animal energy. One is that a substance can not be utilized by a living cell unless it has been assimilated and transferred into organized cell substance. Liebig was the author of this theory and Pfüger most vigorously defended it. On the other hand, Carl Voit claimed that in higher organisms the principal supply of fuel material is furnished to the organs by the blood. The albuminous matter carried to the organs was named by Voit "circulating proteid." Opinions on the subject are still divided and it is possible that in a way both views are correct.

Since there was some foundation for the view that the process of autolysis is the one which controls tissue disintegration, it seemed important to make clear whether or not the mechanism is capable of breaking down albuminous matter derived from other sources than that of its own body substance. The first observation in this direction was made by Theobald Smith, who noted that fresh tissues removed from the organism under aseptic conditions were capable of digesting gelatin. On the other hand, Martin Jacoby¹¹ noted that during the process of liver autolysis, of the proteids, only the globulins suffered a disintegration; and in a later work he observed that the self-digesting liver was completely incapable of digesting lung tissue. Thus, on the basis of this work, one would be led to the view that the process of autolysis is incapable of causing the digestion of circulating proteid, and that the two processes are totally independent one of another. However, Hedin⁴ has shown that the spleen possesses the power to digest not only its own proteid material, but also the proteids of the blood. Thus the question still remains an open one.

PRODUCTS OF TISSUE DISINTEGRATION.

The work thus far reviewed possessed primarily theoretical interest only. It aimed to elucidate the mechan-

ism controlling the disintegration of tissue components in the living and in the surviving organs. Nevertheless a detailed knowledge of the products of tissue autolysis is of importance from the standpoint of practical medicine. In the human organism, as well as in that of many animals, all substances which are consumed as food and nourishment, no matter how greatly they differ in their chemical composition, are finally broken down into a few very simple bodies which are rejected by the organism through the kidneys, bile and other excretory mechanisms. Urea and carbonic acid are the two substances into which nearly all foodstuff is transformed. In a complex organism the metamorphosis is a gradual process. Before a nitrogenous substance is transformed into urea it undergoes numerous degradations. Before sugar is oxidized to carbonic acid it suffers numerous changes. Further, it is not improbable that in a very complex organism individual organs are concerned only in one definite phase of the transformation, leaving the other organs to continue and to complete the work. In his recent address on this subject Professor v. Noorden¹² pointed out that the information regarding the nature of intermediate products of metabolism, as well as the seat of their formation, is lacking. Attention of investigators has turned to the study of the products of autolysis of various organs in the hope of filling in the gap in our knowledge of the mechanism of nutrition and of self-preservation of the organism.

However, the study of the substances arising in the course of autolysis was preceded by very active work on the normal composition of tissues and tissue components. Indeed, it was to be expected that within the body tissue constituents would break down into their component parts. Recent years are marked by astonishing progress in the knowledge of the chemical nature of tissues. It was owing to this progress that the study of autolysis was made a comparatively easy matter. As already stated, the principal tissue components are albuminous matter, sugars and fat. The changes which each one of these components undergoes in the course of self-digestion has been the subject of special investigations.

Under the term proteid is generally understood the substance which represents the most important and most characteristic part of living matter. It is colloidal in nature and is composed of various nitrogenous acids. On heating proteid with strong acids or alkalies, the original substance disappears, giving rise to the nitrogenous acids. Of those already known are the following:

Glycocoll.	Lysin.
Alanin.	Arginin.
Aminovalerianic acid.	Histidin.
Leucin.	Prolin.
Glutamic acid.	Tryptophan.
Phenylalanin.	Cystein.
Tyrosin.	

Of the proteids, one group attracts special attention. Its members are present in greatest quantity in the nuclei of all cells, and it has been assumed that the function of the nucleus is closely associated with the presence of these substances. They are named nucleins, nucleoproteids, nuclealbumins, etc. They are more complex than ordinary proteids, containing in their molecule, besides the usual constituents, a body termed nucleic acid. This acid is composed of substances to

which a considerable rôle in the pathogenesis of disease has been attributed. Its components are as follows:

Phosphoric acid, carbohydrate, thymine, uracil, cytosine, adenine, guanine, hypoxanthine.

Normally, components of simple and complex proteids occur as such in tissues in very insignificant quantities. But it is found that in the course of self-digestion an organ may undergo such deep changes that nothing remains of its original structure, in its place the following substances appearing:

	Pancreas	Liver	Spleen	Kidney	Testes
Glycocoll	+	+	+	+	+
Alanin	+	+	+	+	+
Aminobutyric acid	+	+	+	+	+
Aminovalerianic acid	+	+	+	+	+
Leucin	+	+	+	+	+
Glutamic acid	+	+	+	+	+
Aspartic acid	+	+	+	+	+
Pyrolidim carbonic	+	+	+	+	+
Tyrosin	+	+	+	+	+
Phenylalanin	+	+	+	+	+

A glance at the table shows clearly that the action of the autolytic process in organs is as powerful as that of strong acids combined with high temperature. Nearly all the products which are obtained on prolonged boiling of proteids with strong mineral acids arise also in the course of autolysis. However, there are noted some differences in the two processes. If it be allowed to name substances appearing on cleavage with mineral acid as primary cleavage products, the distinction may be made that on autolysis the primary products undergo further transformation. It is a matter of convenience to discuss the points of difference according to the three principal groups of substances in which they occur, namely: 1. The nitrogenous acids containing only one nitrogen in their molecule, monoamino-acids. 2. Acids with more than one nitrogen in the molecule. (The substances of this group arising from proteid cleavage were named by Kossel hexon bases. They generally possess basic properties.) 3. Substances resulting from the nuclear degradation, nuclein derivatives or nuclein bases. The most appropriate method for investigation was: First, to study the products obtainable on boiling organs with strong acids; second, to study those arising on autolysis of the same organ, and, finally, to analyze the substances appearing on boiling with strong acids of organs previously subjected to self-digestion.

On acid cleavage all the amino-acids are obtained which are known to appear on the breaking down of proteid material. Among the end-products of self-digestion of the pancreas, Emerson¹³ discovered oxyphenylethylamin, which is not known to be present in the proteid molecule, and which may be regarded as a secondary product derived from tyrosin. Further, on autolysis of various organs the formation of glycocoll was not observed, and prolidin could be demonstrated only in a few experiments. It should be remarked that the present methods of analysis of amino-acids are not fully satisfactory and too much weight should not be attached to the results thus far obtained. However, the results of the analysis of the amino-acids obtained from the fresh and from the self-digested glands seem to indicate that in the course of the latter process some destruction of the substances takes place. This may be

seen from a table showing the results of experiments not yet published, although completed:

	Fresh spleen. 5 pounds. 5.700 8.6	Autolysed spleen. 5 pounds. 0.700 1.7
Glycerol		
Alanin		
Aminobutyric and amino valerianic acids	5.25 14.75	5.00 12.0
Leucin	2.24	0.8
Aspartic acid	3.12	1.25
Glutamic acid	1.15	1.33
Phenylalanin	Present.	Present (inactive).
Protein		

The knowledge of the further phases of amino-acid metamorphosis is rather meager. Stolte¹⁴ has shown that amino-acids exposed to the action of tissue extracts give rise to ammonia, and Magnus-Levy¹⁵ has demonstrated the formation of fatty acids in the course of autolysis. Diamino-acids and other basic substances of the proteid molecule suffer a similar disintegration. Thus, on prolonged autolysis of the pancreatic gland or of the gastric mucosa, the formation of diamins from diamino-acids, a process analogous to the transformation of tyrosin into oxyphenylthylamin, was observed by Lawrow,¹⁶ Langstein¹⁷ and by myself.¹⁷ It has also been noted that a very considerable part of the diamino-acids suffers a more complete disintegration. Thus five pounds of fresh spleen yield on hydrolysis 3.2 gm. of arginin and 2 gm. of lysin and the same quantity of digested glands only 1.5 gm. of arginin and 1.2 gm. of lysin. The mechanism controlling this degradation was explained by the brilliant discovery of Kossel and Dakin.¹⁸ These authors have demonstrated in various organs the presence of a special enzyme whose function it is to decompose arginin into urea and diaminovalerianic acid. The same enzyme was found by Shiga in the yeast cell.

(To be continued.)

IRRIGATION OF THE ABDOMINAL CAVITY.

FROM A BACTERIOLOGIC STANDPOINT.

J. WALTER VAUGHAN, A.B., M.D.

DETROIT.

The mortality in cases of peritonitis depends on two things—first and foremost, the virulence of the infecting germ; second and of almost equal importance, the area involved. Given the same organism, capable of forming the same toxin and the same amount of toxin, the severity of the disease will depend on the size of the abscess, i. e., the area involved. In an article by Young¹ the opinions of twenty-five of our foremost surgeons were given on the advisability of flushing out the abdominal cavity in cases of acute diffuse suppurative peritonitis; "fifteen were in favor of irrigation, while ten opposed it." Those who support irrigation claim that they wash away toxic material which would otherwise be absorbed, while those who oppose it certainly have a much better mortality record to uphold their method of treatment.

The study of bacteriology until recent years has dealt mainly with the morphology of organisms and their cultural characteristics. During the past few years, however, we have been enabled to study bacteria from the standpoint of their chemical nature, because of the fact that they have been grown and obtained in large amounts at one time. The Roux flask was the first step

toward this end, and the final result, whereby great quantities of a given germ could be harvested, as a farmer harvests his wheat, has been obtained by means of the large tanks of V. C. Vaughan. To obtain a good growth by either of these means the first and essential requirement, after the medium has been rendered sterile, is to spread a thin layer of the germ substance equally over the surface of the medium. This is done by means of water suspensions of the germ—beef-tea cultures.

The peritoneal cavity may be compared to either the Roux flask or the tank. It is a large sterile cavity under ordinary conditions, but when danger threatens in the form of perforation from appendiceal or other causes, it attempts to protect itself by the formation of adhesions, and thus limit the area wherein the germ can grow. The test-tube is formed as compared to the tank. In animal experiments, where the germ is injected directly into the peritoneal cavity, the animal invariably dies, no protecting adhesions are present and there is a general diffuse peritonitis. The peritoneal cavity has not been forewarned; a large amount of a watery suspension of the given germ has been suddenly thrust into it, and the result is inevitable. In the human body also we find many cases in which perforation takes place almost immediately after the first symptoms; the peritoneum has been unable to protect itself, no adhesions are formed, and we have what is termed acute diffuse suppurative peritonitis. Those who advocate irrigation say that they wash this infectious material out of the abdomen. In reality what do they do? They form a watery suspension of the germ present and force it to every part of the abdominal cavity, thereby causing a true general peritonitis. The test-tube or flask has been changed into the tank and the harvest will be proportionately large.

A general peritonitis, and by that I mean a condition in which all parts of the peritoneal cavity are involved, is a rare and, I believe, impossible condition unless brought about by some such method as the above. Anatomically the cavity is too well divided to permit of an infection of its entire surface through even the most rapid of perforations. The area involved will undoubtedly be large, but let us consider the adhesions formed as the advance guard of the defense, and we shall still have the natural anatomic boundaries as the reserve, when the advance has not been able to cope with the invasion. Roughly, from this standpoint, the peritoneal cavity may be divided into at least three compartments. The pelvic, that below the transverse colon, and that above, the latter of which may again be divided into two, one of which we will term the gall-bladder region and the other the perigastric. In the female the pelvic region is happily more distinctly separated from the abdomen than in the male. From the standpoint of extension of infection the sigmoid may here be regarded as the dividing line. The adhesions between the sigmoid and surrounding structures in fully 90 per cent. of cases are means of preventing the infecting process from extending upward and invading the true abdominal cavity. When abscess formation fails in appendiceal or typhoid rupture the transverse colon is the natural barrier to a further extension of the process upward. Why, then, should we bathe that part of the peritoneal cavity above with a fine suspension of fecal matter and infectious material by means of irrigation? In cases of perforation of gall-bladder or perforating ulcer of either pylorus or duodenum the upper strait is involved—that above the transverse colon. No other part of the abdominal cavity has such definite barriers

to the extension of any infectious process as the region of the gall-bladder and pylorus. E. W. Andrews² says:

There is no part of the cavity which has such invariable boundaries as the gallstone surgical field. Unlike most parts, it is not subject to the floating in or intrusion of other viscera. Its surroundings, to a certain extent, shut it off and prevent it from draining into or out of the rest of the cavity. In form it is a triangle, bounded above by the liver and appendages, below by the colon and mesocolon, and to the left by the stomach, gastrophatic omentum and duodenum. . . . This space can also be conceived as a spherical triangle, or as a pyramid, with its base on the abdominal wall, and its apex in the foramen of Winslow.

Who now would think of carrying infectious pus over these natural bounds and into the surrounding cavity by the aid of irrigation? Yet the same rule holds good for any portion of the abdomen and is equally true of appendiceal rupture and perforations in typhoid.

The reaction caused by such great mortality following flushing of the abdominal cavity in acute diffuse suppurative peritonitis has come in the method of treatment of which Ochsner was the first and foremost advocate—absolute rest with no operative interference—thus allowing Nature to do her best. This after all is what the treatment consists of, and when Nature is undisturbed how does she attempt to contend with the invasion? Pathology teaches us that the local changes are first a serous exudate which later becomes fibrinous in character. This we know is the means by which the infection is walled off and abscess formation occurs. Why, then, should we wash this exudate away and thus prevent, or at least retard, such a result by means of irrigation? In the local exudate, as well as in the entire blood stream, a great increase in the number of leucocytes can always be observed, and while as yet we do not fully understand what part these leucocytes play in the resistance to infectious processes, yet we know that they play a part of much importance in the successful issue of these cases. These also are washed away when irrigation is employed. Outside of this, Nature protects with chemical substances which we term antitoxins, but we look upon these not as a local product to resist infection, but rather as a general one. However, the amount of such a substance required will vary directly with the intensity of the infection, which may be said to be governed partially by the area involved.

It is a common clinical observation that shortly after irrigation of any abdominal abscess there is a noticeable rise in the temperature of the patient. This we ascribe to increased absorption, that is, we have not only washed out the debris of dead cells, but the protecting exudates covering the peritoneal surface have also suffered and new exudates must be formed before the toxic products are again separated from direct contact with the blood stream and lymphatic channels. A given organism will soon die out if kept in the same test-tube, but if new media be constantly added or frequent transplantation take place its life may cover a greatly extended period.

Realizing then that Nature's most efficient safeguard is in the formation of adhesions and that the percentage of cases in which these cause permanent after trouble is very small, let us consider how we can best aid in what Nature has failed to do. From a bacteriologic standpoint irrigation is entirely contraindicated. The surgeon will tell you when the abdomen is opened because of any infective process that drainage is the object sought. A large perforated rubber or glass tube furnishes the best means of obtaining the freest drainage, and this is frequently used and with most satisfac-

tory results. However, always in conjunction with this and sometimes alone, one or more gauze drains are inserted into the abdominal cavity. This is done because clinical experience has taught the surgeon that his patient will do better and that recovery in a greater percentage is assured if the gauze drain be used. Given the choice between gauze and tube drainage and, I venture to say, by far the majority of surgeons would choose the gauze, and their reason would be that clinical experience proves that the mortality is far less when this form of drain is used. Now why should this be so? To my mind the answer is found by reverting again to that second factor in the causation of the mortality, namely, the area involved. At present we have no substance which is so effectual in the stimulation and formation of adhesions as sterile gauze. The gauze drain helps Nature to build up that safeguard which she is called on to supply, and hence helps to limit the area of infection. After three or four days this drain, which has played so useful a part in the limitation of the area involved, may become an absolute menace, for when the exudate has become dried upon its surface it plays the function more of a cork than a drain. But by this time the adhesions are well formed and the tube should be substituted for the gauze, since free drainage is now the essential in order that the pressure within the abscess may be as small as possible, and thus render slight the danger of infecting that portion of the abdomen without the abscess by rupture of the same.

It is my opinion that the habit of irrigation in infectious conditions of the peritoneum is a pernicious one, absolutely without either scientific or clinical endorsement, and one which appears to be as difficult for the general surgeon to give up as anterior suspension or fixation has been for some gynecologists. Many of the leading surgeons have abandoned irrigation in peritonitis from appendiceal trouble, it is true, and their results alone should cause others to follow in their steps. Why should the same principle not be adopted in typhoid perforation, and, indeed, perforations from all other causes? I believe that if such a course were to be adopted the present mortality would be markedly reduced.

1939 Woodward Avenue.

THE CONSERVATIVE SURGERY OF THE TUBES AND OVARIES.*

ANDREW STEWART LOBINGER, A.B., M.D.

LOS ANGELES.

It is twenty years since Schröder first advocated the preservation of the remnant of normal ovarian substance in excision of small cysts of the ovary. August Martin, about the same time, reported a number of cases in which normal portions of the tube and ovary were preserved and the degenerated portion removed. W. M. Polk a year or two later presented the same subject to the American profession and submitted his brilliant results in the conservation of these structures. Since that time contributions have been made to this field of work by Dudley, Kelley, Morris and others, showing definite results in relieving pain, establishing normal menstrual function, and, in a number of instances, being rewarded by seeing the patient bear children.

There could be slight excuse for calling attention at

* Read before the San Bernardino (Cal.) County Medical Association.

this late day to the many ingenious procedures for the partial restitution and preservation of these structures so vital to the happiness and well-being of women, were it not a fact that these possibilities are still grossly and continually disregarded. There is scarcely a week passes without the painful evidence of some patient suffering a loss, to her irreparable, of either one or both ovaries and tubes, ablated for ovarian neuralgia, hydrosalpinx, obliterating salpingitis, or worse than all possibly, simple ovarian cyst with minor adhesions.

The mental distress which overcomes these unfortunate subjects in the sudden and artificial induction of the menopause, the deprivation of the possibilities of motherhood, the definite belief that they are to become shattered and to lose those delicate and essential elements which distinguish their sex—these realities and fears are sufficient in themselves to cause any surgeon to reflect on his responsibilities. And no one of even moderate experience will question the frequency of the appalling consequences of this crude and wretched work.

The prevalence of long obsolete procedures in surgical technic is no fault of our masters, who have filled the literature of every language with a modern gospel which is free to all of us. The fault is ours and lies stark and accusing at our own threshold. We are not guiltless, if in our apathy we have not hardened to good teaching nor heard the warning for him whose crass ignorance shall cause innocent ones to suffer through long and helpless years.

Improvement in this field of work is to be looked for in a more patient and careful study of the pathology of ovarian and tubal disease. It is necessary to get away from the fads which have misled us and drawn us unthinkingly after false teachers, who would find in the extirpation of a vital and essential organ the relief from a painful symptom. It is necessary to distinguish between surgical procedures which are mutilating and those which are conserving and remedial. Only by thoughtful and studious consideration of the physiology and physiologic chemistry of these structures and the relative degrees of existing pathologic change can one found a judgment which has enduring value.

The wild claims of the advocates of Battey's operation are fresh in the minds of all of us. Many, if not most of us, I daresay, have been blind followers of the blind in this grievously erratic doctrine. We can atone for these errors only by a persistently earnest effort to analyze our cases with greater conscience and precision, and to choose a surgical procedure which will the most perfectly restore the organ to its normal function.

It is beyond the limits of this paper to discuss the multiform influences contributing to disease of the pelvic organs. Outside of the violences of incorrect diet, bathing, clothing, exercise and social dissipation, there is that great trinity—septic metritis, gonorrhea and tuberculosis—which forms the sum total of concrete disease of the tubes and ovaries.

It may well be said at this juncture that any and all of these conditions might be prevented, and that it were more philosophic to deal at length with measures looking to the prevention of these potent infections than to efforts to preserve the shattered remnants of their destructive work. We need have no quarrel with the sanity of this idea, and preventive medicine has no fairer field for its cleverest effort, but the surgeon is still the latest to be called and is confronted by a complicated pathology which admits of but one appeal.

CONSERVATION OF THE OVARIES.

This discussion need not deal with those large ovarian

cysts, now so rarely met, in which all ovarian substance has perished, nor with extensive dermoids, hematomata, parovarian cysts or that extremely rare neoplasm, fibroma of the ovary. Carcinoma, tuberculosis and abscess call for the total extirpation of the affected ovary and, in the first two, frequently of the uterus and adnexa. It is possible, however, to save an ovary partially destroyed by a small abscess. It is just as rational and defensible as to spare the parotid, mammary gland or testicle under like circumstances.

The commonest affection of the ovary calling for surgical relief is the small cyst. These cysts usually occur in numbers and they vary greatly in size. They may be pseudo-retention cysts—unruptured Graffian follicles—or true cystic degenerations of the corpora lutea. In any case they add a preternatural weight and create a tension in the tunica albuginea which results in a dragging burning weight and in so-called ovarian neuralgia. I have seen many cases in which this excessive weight threw the uterus backward out of its normal axis and held it tight against the rectum in the hollow of the sacrum. Often these large cystic ovaries become imprisoned deep down in the cul-de-sac of Douglas, acting like spherical valves, the force of whose suction not only keeps the vessels in the tube, ovary and broad ligament congested, but produces and maintains a dorsal version which is both painful and obstructive. In almost every instance the tunic will be found greatly thickened, causing ovulation and the menstrual period to be very painful.

A great deal was said in former years concerning the "cirrhotic" ovary. We know now that this is a myth and that what was designated ovarian "cirrhosis" was nothing more than a somewhat distinctly defined collection of the scars of ruptured follicles. No doubt there are women in whom the ovaries show a tendency to contract and, through the physiologic process of ovulation, to lose parenchyma which relatively gives the appearance of increase of stroma. That condition, however, is no more pathologic nor is it more frequent than the hypertrophic ovary which I have met repeatedly and which in some cases I have observed to be twice the size of the normal organ. Microscopic examination shows a relative increase in the reticulum in the one case, in the parenchyma in the other. Neither condition is pathologic, although I have found that removal of at least half of the hypertrophied ovary gives immediate relief from the weight and burning. Many so-called cirrhotic ovaries are doubtless the remnants of previous small ovarian abscesses or the result of adhesive bands from septic inflammation of the uterus and tubes. In these cases the irritating scar may be resected and the normal portion of the ovary left, and this may be laid down as the rational surgical procedure in every instance of ovarian pathology, save the exceptions heretofore mentioned. It may be stated dogmatically that oöphorectomy, except in this restricted sense, is not only obsolete, but that it is utterly wrong and unjustifiable, and this doctrine will apply to at least 90 per cent. of all pathologic ovaries.

The technic of excision of the cysts and degenerated portions of the ovary is not difficult, but calls for nice dissection and delicate suturing with fine plain catgut. It will be found that in many instances the walls of these cysts can be peeled out with fine dissecting forceps as soon as the tunic is incised. The incision should pass through the superior edge in the long axis of the organ and it will be found that at the base there is much ovarian tissue which is absolutely normal.

I can recall many patients operated on for tuberculosis or for septic destruction of both tubes and apparently of both ovaries, in whom it was possible to leave ovarian substance at the base of one or both ovaries not larger than an olive seed. These women all began to menstruate at periods varying from two to six months after the operation and with but slight irregularity. There has not been one of them in whom this function has been effaced, and within a year all of them became as regular as the average normal woman.

In one case of caseous destruction of the entire left tube and ovary and of the right tube, and all but the submerged base of the right ovary, from tuberculosis it was possible to save the merest portion of the base of the right ovary. This patient has had irregular, and at times, suppressed menstruation for fifteen years and has also suffered from pulmonary tuberculosis. Before the operation she menstruated irregularly at intervals of from two to four months. After her operation there was no sign of return of the period, except a headache from congestion, for three months. She then flowed slightly for a day and a half, but not until the sixth month was the menstruation fully re-established; even then it was attended by some pain. Now, two and a half years later, menstruation occurs regularly, lasts three days, and gives as little discomfort as is usual in normal women.

In a number of other patients the destruction of the ovary has been less than in this case and the re-establishment of the menstrual function has been relatively earlier and less eventful. In a still larger class of patients one of the ovaries may be almost or quite totally destroyed and the other partially or wholly normal. In such the excision of the diseased tissue leaves no incident of note in the perfectly normal menstrual cycle.

Ovarian grafting in young women who have previously been subjected to ovariectomy is still in the experimental stage. Knauer's experiments on rabbits in 1896 showed that autotransplantation of an excised ovary within the broad ligament resulted in continuance of ovulation. Hetero-transplantation has resulted in degeneration of the ovary thus transferred from one animal to another. In a recent contribution by Robert T. Morris, comprising a résumé of the latest work in this field, including his own, these conclusions are drawn:

1. When the ovaries are removed from an animal and then replaced at some point near their original site or even at distant points, the tendency is for the ovary to continue its function of developing ova and of furnishing its internal secretion. Such transplanted ovaries may continue to do normal work for an indefinite period.

2. When ovaries are removed from one animal and transplanted into another animal of the same kind which has had the ovaries removed, the tendency is for the grafted ovary to undergo a degenerative process. The graft will continue to furnish ova and internal secretion for several months in some cases, but at the end of a year we often find the grafts fatty and apparently useless. We assume that the serum of one animal is destructive to the introduced tissues of another animal of the same sort. My present line of investigation is toward making one series of rabbits immune against the serum of another series and then exchanging the ovaries of the two series. If this can be accomplished, ovarian grafting will be placed on a plane of usefulness much above its present one.

As the possibilities of conservative surgery on the ovary are better understood we shall have fewer subjects requiring transplantation. In fact, it is simply the substitution of a rational artistic technic for a crude and ruthless sacrifice of vital structures.

CONSERVATION OF THE TUBES.

In the uterine tube we have a structure which in both its histologic and anatomic characters becomes at once a more complex problem than the ovary. Partly on account of this involved pathology the ovary has frequently been sacrificed with the diseased tube. This practice has doubtless grown from the fallacy that if the tube be partially or hopelessly destroyed the ovary is likewise in a hopeless condition and should be removed also. No more pernicious doctrine than this could prevail. Each organ must be considered and treated with regard to its own pathology, and the fact that certain organs are anatomically contiguous and may be closely related by blood and lymph currents and nerve supply is by no means just cause for sacrificing both organs when but one is diseased. There are many mild infections outside of the strictly pyogenic, gonorrheal or tuberculous that may cause the lumen of a tube to become obliterated. I have often found the isthmus constricted and the *ostium abdominale* partially closed in young unmarried women, with neither a history nor pathologic evidence that any infection, however mild and innocent, could have occurred. Yet at some time when the uterine mucosa was most susceptible a slight endometritis had extended to the tubal lining and through successive attacks had produced the hyperplasia necessary to cause occlusion.

There is also good reason for the belief that bacteria from the appendix on the right and from the epiploic processes of the sigmoid on the left have been definite factors in the closure of the ampulla at the fimbriated extremity. Whatever the etiology of these milder infections, on account of which the tube ceases to be patulous, we have in this obstruction a cause of sterility as actual and permanent, until relieved surgically, as from a septic or gonorrheal infection. And it should be remembered that fully a third of the patients in private practice presenting themselves for relief from sterility are suffering from the results of these milder infections. The frankly septic and gonorrheal infections very naturally cause the most destructive and complex deformities of the tubes and call for a correspondingly radical treatment. Fortunately for the operator, unfortunately for the fate of the tube, the best practice that is now known to us is to await the subsidence of the acute process before surgical interference is justifiable. Whether we shall ever venture as a rule of practice to treat these abscesses early before extensive destruction of the tube occurs is doubtful.

A better understanding of the means of arresting the infection before it passes in any degree beyond the uterine mucosa is necessary. This gained, the conditions in the tube will be found more amenable to early cleansing and drainage and by so much the early treatment of sub-acute septic and specific infections of the tube will be practicable. Even as it is one is continually surprised to see how remarkably well these extensive infections clear up and leave tubes which seem hopelessly deformed, astonishingly free from evidences of damaging inflammation. It may be necessary to do more than one operation on these structures. It will always be necessary to apply the most discriminating judgment and careful technic in regard to the incision, the matter of drainage and in arriving at a decision as to what portion, if any, may safely be removed. Yet it is most gratifying to find in how many instances the surgeon is well rewarded for the care and pains taken to save his patient these priceless structures.

In tuberculosis—an infection of the tube which we

are identifying far more frequently than heretofore—little as yet can be offered of a conservative character. Theoretically there should be no justification for sacrificing an apparently sound ovary or tube. If one is infected and the other not it would seem to be reasonable practice to leave the sound tube, even though a later infection should occur and a second operation be necessary. This doctrine would be beyond controversy did we actually know that the endometrium and the lining of the sound tube were uninfected. In the light of our present methods, however, we can not know, and hence we must be guided by clinical experience; this has taught us that when one tube becomes manifestly tuberculous infection of the other is almost inevitable and that in this infection the uterus is frequently first. With this pathology we now know but one safe course of action—total extirpation. The future should hold something better than this.

The technic in tubal surgery must depend largely on the character and degree of infection and the extent of destruction and deformity. In simple stricture at the isthmus, resection of the isthmus and the anastomosis of the ampulla with the proximal end of the tube near the cornu, offers good results. A cord of heavy plaited silk should be anchored in the ovary and the other end carried down through the uterine cavity to a gutta percha bobbin in the vagina to insure the mucous tract remaining patulous during the repair of the anastomosis. I have known pregnancy to occur within three months following this procedure.

When the mouth of the tube has closed by a sealing over of the processes of the fimbria the adhesions, which are usually thin and delicate, should be opened up, the cavity of the ampulla carefully syringed out with salt solution and the edges of the released fimbria folded back over the tube like a cuff and tacked there with interrupted stitches of fine catgut.

When the tube is angulated or kinked by fine dense bands these should be snipped and the tube straightened out, and if a stricture persists the dorsum of the tube should be laid open and the lumen given the usual toilet. Attempts to probe the tube are usually so fruitless that such injury as is sure to result should be avoided. Careful syringing with salt solution in a fine syringe is far safer and more effective.

In tubes which have been septic or gonorrheal and in which active cocci no longer exist, or in mild types of hydrosalpinx, the occluded tube should be opened up, cleansed and the cystic portion utilized as an ampulla. If perfectly free from infective material the dorsum of the obliterated portion of the tube may be laid open and a silk cord passed downward as in the case of anastomosis already described. Frequently these tubes will be found patulous just proximal to the barrier of the cyst wall and the incision may cease a line or two beyond it.

When the tubes are large pus sacs it has been customary to remove them and, commonly, the uterus. It remains to be seen if we shall not be able to do better than this by carefully and properly applied drainage in a series of operations. It can not be denied that so far little of merit in this direction has been recorded; yet if we were to quail at a septic tendovaginitis in the hand and wrist, as we do at conserving pus tubes in the pelvis, what a melancholy showing we should have. Possibly a little more patience, a little more plodding, a little more dogged belief in Nature's regenerative power when nicely and intelligently aided, would be rewarded here as elsewhere, in fields more difficult but not more worthy.

What has been said of preserving the tube when impaired by infection will apply with equal force to tubes changed by ectopic pregnancy. A tube should never be sacrificed if it is possible to save it or even a portion of it, for the normal one may suffer soon in like manner and both thus perish.

In every instance of conservative work on the tubes and ovaries the uterine cavity should be thoroughly curetted and cleansed, since it may be necessary to establish and maintain communication for several weeks between the abdominal cavity and vagina through the uterine canal. That this can be done with perfect safety has been repeatedly proved, but the price is strict asepsis, both as to the sterility and toilet of the tubes and after toilet of the vagina.

It will often be found necessary to shorten the uterine round ligaments to correct version and descent, and this should not be overlooked.

The results of value in a certain procedure are the end results. I know of none more positive or beneficent than in this field, provided careful judgment and attention to minute detail is faithfully observed. My hopes will be more than realized if this paper shall serve to revive a just interest in a field by no means worked out and one in which conservatism will be of much benefit to the race.

THE VALUE OF ALCOHOL IN CARBOLIC ACID POISONING.

A CLINICAL AND EXPERIMENTAL STUDY.*

THOMAS WOOD CLARKE, M.D.

Resident Physician, the Lakeside Hospital.

AND

EDGAR D. BROWN, Ph.D., M.D.

Demonstrator of Pharmacology, Western Reserve University.
CLEVELAND, OHIO.

1. INTRODUCTION.

The use of alcohol as an antidote in carbolic acid poisoning was first brought before the medical profession by Dr. Seneca D. Powell of New York City. At his clinical lectures, from about 1894 on, he was in the habit of demonstrating his theory by such an experiment as washing his hands in pure carbolic acid and then in alcohol, and had even filled his mouth with the pure acid, and by quickly rinsing it with 95 per cent. pure alcohol had experienced no harmful results. From these experiments he made the statement that alcohol is an antidote to carbolic acid, and suggested its being used internally in cases of poisoning. The results of his five years experience were reported to the Medical Society of the County of New York Feb. 27, 1899, and appeared in the reports of this society.¹ He, however, had had no practical experience in poisoning cases and goes no further than to mention a case of which he had heard of a one-month-old infant, who, after swallowing the strong acid, had been given a teaspoonful of whisky, though apparently moribund, and had recovered temporarily. Furthermore, this child, having died eight days later of pneumonia, showed no signs of an eschar in the stomach.

The first mention of alcohol as an antidote from a clinical standpoint is in the report by Donald B. Fraser² of a patient who took an ounce of the pure acid in a glass of whisky, and, though unconscious for eight hours,

* From the Medical Service of the Lakeside Hospital and the Pharmacological Laboratory of Western Reserve University.

1. Powell: Medical Record, New York, 1899, vol. iv, p. 372.

2. Fraser *Ibid.*, 1899, vol. xlviii, p. 741.

eventually recovered, repeated lavage with water having been resorted to. He then states that alcohol is apparently a true antidote in carbolic acid poisoning. Whether the author was familiar with Powell's work, at that time unpublished, he does not state.

The credit of first using alcohol in poisoning cases seems to be due to Dr. J. Drysdale Buchanan,³ who used lavage with two quarts of 35 per cent. alcohol for a patient who had taken one ounce of the acid.

Since these early reports there have been a number of isolated cases in the literature from which the most positive conclusions have been drawn. For example, Kelly⁴ in 1899, after reporting one successful case, states that "alcohol is undoubtedly the best antidote for all cases of carbolic acid poisoning, and, indeed, is an absolute antidote." Phelps⁵ on the strength of Powell's work, says: "In cases of carbolic acid poisoning, if immediately after the administration of the poison, alcohol was thrown into the stomach the poisonous effects of the carbolic acid would at once be neutralized." Pinkney,⁶ after reporting a fatal case, says: "The amount of carbolic acid left in the stomach and intestines when alcohol came in contact with it was rendered harmless, and the general action of the already absorbed poison was checked immediately." Finally, Gross,⁷ in discussing the subject, refers to alcohol as a chemical antidote, and says that the reaction forms "a new phenol benzene or aromatic compound having the chemical and therapeutic properties of alcohol."

Two years ago one of us, having been favorably impressed by some of these reports and by good results obtained by the use of alcohol by himself, and other members of the staff of the Johns Hopkins Hospital, in cases of carbolic acid poisoning, introduced the use of alcohol in the emergency room of the Lakeside Hospital. Since that time thirteen patients with carbolic acid poisoning have been admitted to the hospital, for all of whom the alcohol treatment has been used.

2. CLINICAL DATA.

BY T. W. CLARKE.

As all former reports on this treatment have been of single cases, from which, owing to the natural tendency of the profession to report their successful cases only, but slight conclusions can be drawn, it has seemed advisable to report the present series of thirteen cases more or less in full. For permission to use these cases we wish to thank Drs. Hunter Powell, John H. Lowman, Henry E. Upson and Edward F. Cushing, visiting physicians to the Lakeside Hospital.

CASE 1.—Patient admitted at 8 p. m. Dec. 14, 1903, unconscious. Had taken carbolic acid, 3ss, in whisky. There were two burns on chin. Pupils react, breathing heavily. Pulse was so rapid and weak that it could not be counted. Stomach was washed out with two quarts alcohol, 10 per cent., then milk and eggs, Oi, left in stomach. Strychnin, 1/30 gr., digitalin, 1/30 gr., given hypodermically. At 9 p. m. patient was conscious and very noisy; quieted with sodium bromid and chloral, aa5i, by rectum, and slept the rest of the night. Temp. 100, pulse 110, at midnight.

December 15: Some pain on swallowing. Nothing to be seen on examination of the throat and mouth. Temp. 99 to 101.5, pulse 80, resp. 20, urine dark.

December 16: Patient allowed up in wheel chair. Still

slight soreness on swallowing. Physical examination negative. Temp. normal, pulse 70 to 80, respirations 20 to 26.

December 18: Eats well, no difficulty in swallowing. Scar on chin disappearing. Discharged, well.

CASE 2.—Patient admitted 11 a. m. Jan. 17, 1904, having taken carbolic acid, 3ss, shortly before, in glass of beer. Patient was unconscious. Pulse arrhythmic, rate 160. No burns on lips, slight erosion on cheeks. Lavage performed with alcohol, 10 per cent. The washing contained carbolic acid and much undigested food. Milk and eggs, Oi, added and left in. Artificial respiration was resorted to several times. Strychnin, 1/20 gr., and digitalin, 1/30 gr., were given twice in quick succession. Temp. 96.4, resp. 58, pulse 160. At 1:30 p. m. the pulse and respiration became most irregular. Strychnin, 1/20 gr., and digitalin, 1/30 gr., steadied both. Hot water bottles were applied and coffee, 3viii, given per rectum. At 3 p. m. subcutaneous infusion of normal saline, 600 c.c., was given and repeated at 7 p. m., the last containing 7 gm. sodium sulphate. Patient vomited frequently between 4 and 5:45. Patient first showed consciousness at 7 p. m. while the infusion was being given.

January 18: Patient is doing well. Temp. 100.5 to 101, pulse 100 to 110, resp. 30 to 40. The patient looks well and seems but little the worse for her experience. Urine black, slight trace of albumin, no blood, no casts.

January 19: Last night the patient's temperature rapidly rose, and this morning was 105, resp. 70 and pulse 160. Leucocytes, 5,900. The patient is very cyanotic. Sponge baths, strychnin and oxygen ordered. Examination of chest is negative. Urine yellow, heavy trace of albumin, no blood, no casts.

January 20: The temperature has remained in the neighborhood of 105, pulse 150 to 170, resp. 60 to 65. To-day there is a definite pneumonia area over right upper lobe. Over the entire chest there are patches of tubular breathing and large mucous rales. Patient died at 10:30 a. m.

Autopsy showed an aspiration bronchopneumonia and a small, irregular, dark-colored patch in the fundus of the stomach.

CASE 3.—Patient admitted March 4, 1904, 9 p. m. Walked in, said he had drunk three glasses of whisky and then carbolic acid (doubtful quantity). Was quite conscious and rational. On left side of mouth and lower jaw were acid burns. Inside of mouth and pharynx slightly burned. Respirations normal, 28; pulse good, 100 a minute; temperature normal. Stomach was washed with 10 per cent. alcohol, and water, and sent to ward. He showed practically no constitutional symptoms; slept all night after 1:30; pulse 98 to 104, but of good quality. The next day the inside of patient's mouth was blistered. Discharged, cured.

CASE 4.—Patient admitted May 9, 1904, 12:10 a. m. Brought in in ambulance in a delirious condition. Had been drinking and had then taken carbolic acid, 3i. Pulse fairly good quality, 100 per minute. Some burns about the lips. The stomach tube was passed and food particles removed, smelling strongly of phenol. Lavage with 10 per cent. alcohol solution and followed with water. Milk, Oi, and 4 eggs inserted and left in stomach. Patient was given sodium bromid, 25 gr., and slept until morning. Temp. 96.6, pulse 100, resp. 24. The urine the next morning was black, contained a faint trace of albumin and a few hyaline casts, sp. gr. 1038. The next morning patient appeared well; slight eschar on lips; nothing to be seen in throat; some epigastric tenderness. Patient was kept in the ward until May 15 and then discharged, well.

CASE 5.—Patient admitted 5:20 p. m. July 22, 1904. She had been drinking for five days, and at 5 p. m. of the day of admission drank 10 cents' worth of carbolic acid (3i), with suicidal intent. She was taken into a saloon and became unconscious. On admission she was unconscious, cyanotic, breathing heavily, a great deal of mucus protruding from the mouth, vomiting a little. Pulse rapid and small. The face, mouth and pharynx were badly burned. Temp. 98, pulse 120, resp. 30. The stomach contents showed carbolic acid. Lavage with 10 per cent. alcohol, followed by water, and milk and eggs left in place. She was unconscious after reaching the ward, but regained consciousness at 8:20 p. m. Patient dozed

3. Buchanan: *Ibid.*, 1898, vol. lvi, p. 241.

4. Kelly: *Merkel's Archives*, 1899, p. 441.

5. Phelps: *New York Med. Jour.*, 1899, vol. lxi, p. 62.

7. Gross: *Fort Wayne Med. Jour. Mag.*, 1899, p. 73.

all night, waking several times to vomit mucus. The temperature remained elevated for several days, 100 to 101 July 23, 99.5 to 100.5 July 24, 99 to 100 July 25, 26 and 27. The pulse remained at 120 until noon July 23 and then gradually came down to 100 that night, and was 80 on July 26. The respirations from 20 to 30 the first day, 20 after that. The urine was never obtained black, but contained a heavy trace of albumin and many hyalin and granular casts. The leucocyte count the day of admission was 18,400, reds 4,226,000, and hemoglobin 95 per cent. Patient discharged on July 27. The scars on her face were very sore and showed some signs of sloughing. Temperature was 99.

CASE 6.—Patient admitted 2:30 a. m. July 26, 1904. Had taken one ounce of carbolic acid in a glass of whisky. Became unconscious in five minutes, and was sent immediately to the hospital. On admission was unconscious, no sign of burns about mouth or lips; breathing stertorously; pupils small; pulse small, 120 a minute; no vomiting. Lavage with alcohol, 10 per cent., followed with water; after washing, milk and eggs and sodium sulphate, 5ii, were put in through tube. Patient became conscious at 5 a. m. Recovery was uneventful. The urine was dark-brown, acid, sp. gr. 1014, and contained a few hyalin and granular casts. On admission temperature was 97 and rose to 100.2 at 8 a. m., then gradually came down to 99 July 28. Pulse on admission was 118, at night 100, and 70 on the night of July 27. Respirations 32 on admission, at noon 14, and after this 18 to 20. The leucocyte count the morning of admission was 19,500. Patient did well and was discharged July 28, well.

CASE 7.—Patient admitted 8:30 a. m. Sept. 14, 1904. Had taken carbolic acid, 5i. She was unconscious, tongue and lips slightly burned, very weak, cyanosed, breathing stertorously, pupils much contracted. Pulse barely perceptible, quite irregular, 140 a minute. Stomach tube passed and contents showed carbolic acid. Lavage with alcohol, 10 per cent., and then water, eggs, milk and sodium sulphate, 5i, by tube. Strychnin, 1/30, and digitalin, 1/30, given twice within an hour. Intravenous injection of soda sulphate, 2 per cent., 250 c.c. Patient became conscious in two hours. In the afternoon had severe vomiting spell, which was relieved by dilute hydrocyanic acid, 4 minims, and bismuth subnitrate, 10 gr. On admission temperature was 99, pulse 112 and resp. 30. Temperature went up to 100 that night, and then down to normal the following evening. The pulse remained at 110 for 24 hours, and then dropped to 80 and remained in that neighborhood, with occasional flare-ups. Respiration came down gradually from 30 to 20 in 3 days. The urine was pale, sp. gr. 1020, faint trace of albumin, and a very few hyalin casts. Patient suffered considerably from soreness of the mouth and had very little pain in the stomach. No vomiting after the first day. Discharged, well, Sept. 19.

CASE 8.—Patient admitted Feb. 28, 1905. Child, aged 19 months, swallowed an unknown quantity of 95 per cent. carbolic acid three hours before admission. Seen by a physician at the home five minutes later, who washed stomach with alcohol and water. Patient was unconscious when seen at that time. On admission was very drowsy, temperature 101.5, pulse 160. Tongue, pharynx and inside of cheeks very badly burned, white in color. On admission patient was given magnesium sulphate, 5ii, and strychnin, gr. 1/250. March 1, temp. 104, pulse 152, resp. 40. March 2, temp. 100, pulse 160, resp. 20. From then on the temperature varied from normal to 100, pulse from 100 to 150, and respirations from 25 to 30. The child did well, and on March 6, the mouth having healed, patient was discharged.

CASE 9.—Patient admitted on March 23, 1905. The history was that she apparently fainted in an elevator, and poisoning was not suspected for one and a half hours. On admission she was moribund, unconscious, cyanotic, resp. 36, pulse small and weak, 160, pupils dilated, faint trace of carbolic to breath, mucous membranes, gums and palate white. Patient was stimulated with strychnin, 1/20 gr., digitalin, 1/30 gr., and stomach washed with alcohol, 10 per cent., and eggs and milk and magnesium sulphate, 5iii, left in the stomach, 500 c.c. Soda sulphate, 2 per cent. solution, given intravenously. Pa-

tient never rallied and died half an hour after reaching the ward.

CASE 10.—Patient admitted May 5, 1905, in an unconscious condition. Had taken carbolic acid, time not known. Severe burns of the cheek, corner of mouth, lips, tongue and roof of mouth. Pulse weak and rapid. Stimulated with strychnin and digitalin. Stomach washed with 10 per cent. alcohol and water. Eggs and milk, magnesium sulphate, 5i, and sodium sulphate, 5ss, inserted through tube. Temp. 100, pulse 110, resp. 20. Patient was restless after getting to ward, but later slept. Temperature during the day rose to 100.8 and pulse 120, but on the second day temperature became normal and pulse 80. The leucocytes on May 5 were 28,200. Patient had difficulty in swallowing and considerable epigastric tenderness.

On May 7 patient felt well except for the burns on the face, and insisted on going home.

CASE 11.—Patient admitted, unconscious, 9:30 p. m. June 1, 1905. Had taken carbolic acid, 5ii, a few minutes before. Two scars, 4 cm. long, on upper lip; slightly cyanotic; pulse good. Lavage, 10 per cent. alcohol, then magnesium sulphate and eggs and milk by stomach tube. No stimulation. Consciousness returned 10:30 p. m. Next day scars marked on lip and slight on roof of mouth and tongue. Large white patch on right tonsil and posterior wall of pharynx. Larynx inflamed, abdomen rigid and sensitive in upper half. Blood examination: Leucocytes, 11,800; hemoglobin, 83 per cent.; fresh blood normal. Urine greenish, sp. gr. 1020, acid, loaded with hyalin, granular and leucocyte casts. June 4 and 5: Urine, sp. gr. 1015, neutral, no casts. June 5: Discharged, well.

CASE 12.—Patient admitted 3:30 p. m. Sept. 7, 1905. Had taken carbolic acid, 5i diluted with a little water, fifteen minutes before. She had not swallowed all, as the glass was knocked from her hand after two swallows.
